# Teleconnection from seasonal rainfall anomalies in the Indian – W. Pacific ocean (DJF)

from Molteni, Stockdale & Vitart 2015

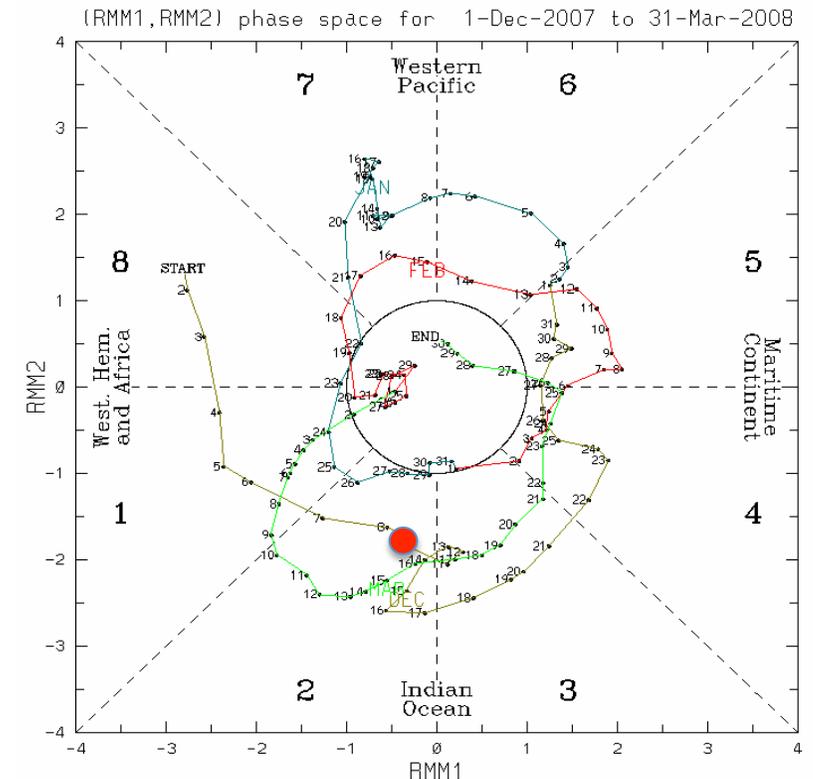

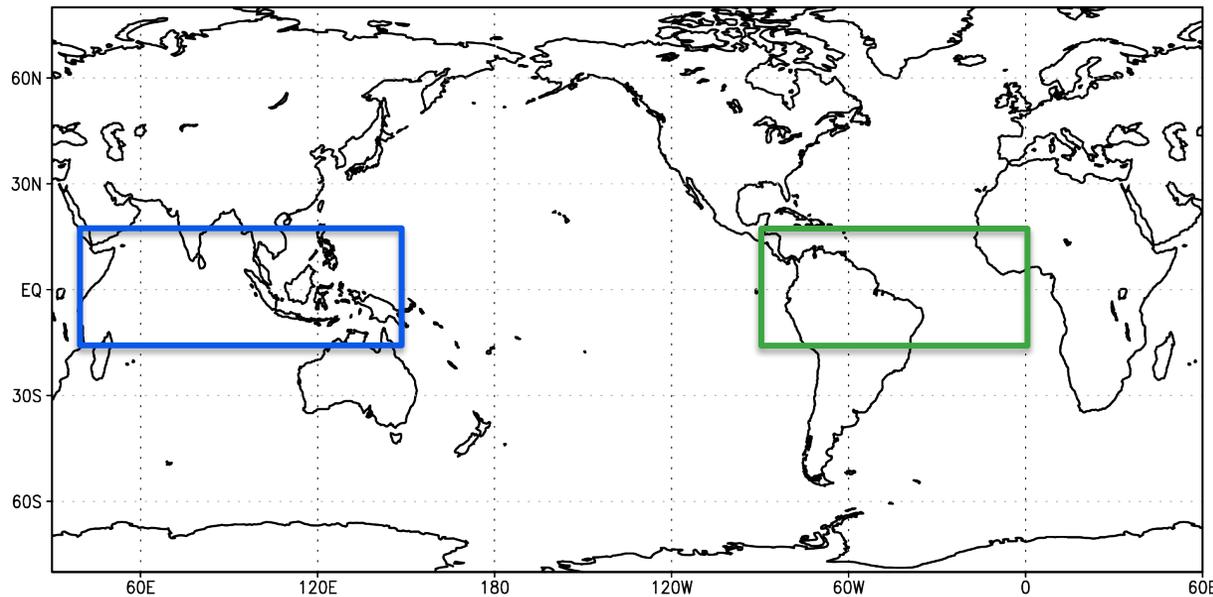

Are these teleconnections important on either shorter or longer time scales ?

- The sub-seasonal time scale (15 ~ 90 days)
- The decadal time scale (see: <https://www.ecmwf.int/sites/default/files/elibrary/2017/17619-tropical-extratropical-interactions-ensemble-predictions-sub-seasonal-decadal-scales.pdf>)

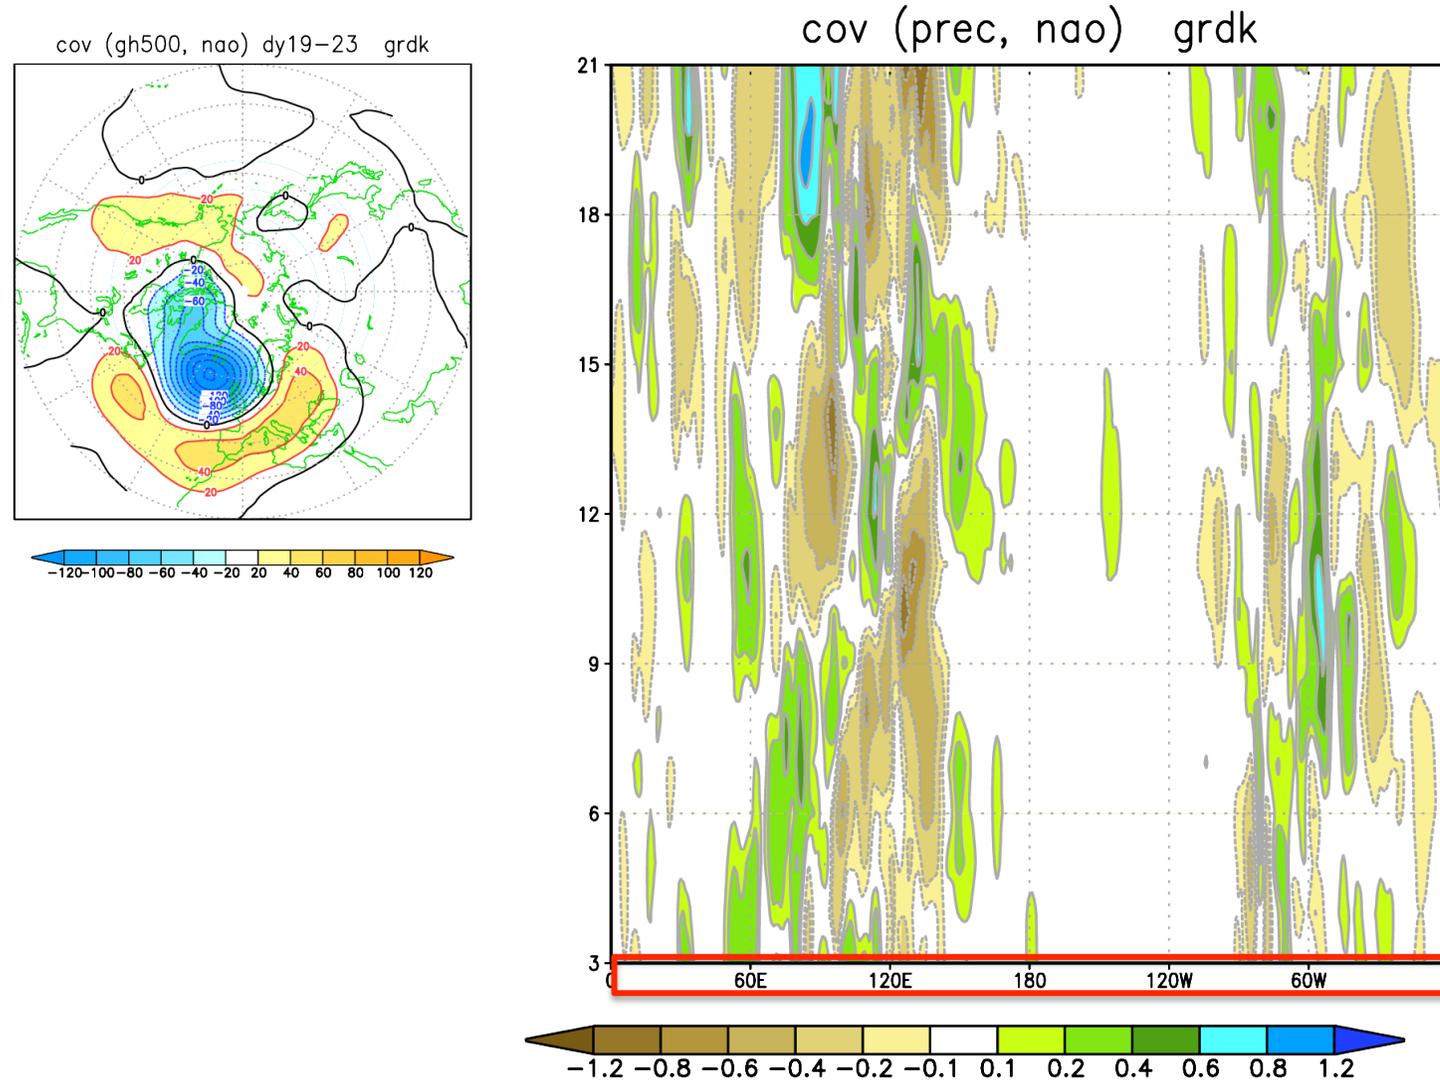

# Experiments with stochastic perturbations to physical tendencies (SPPT) in selected regions (from Sarah-Jane Lock)

Three 51-member ensemble forecasts, start date: 10 Dec. 2007 (MJO phase 2)  
No perturbation in initial conditions, spread induced by SPPT only

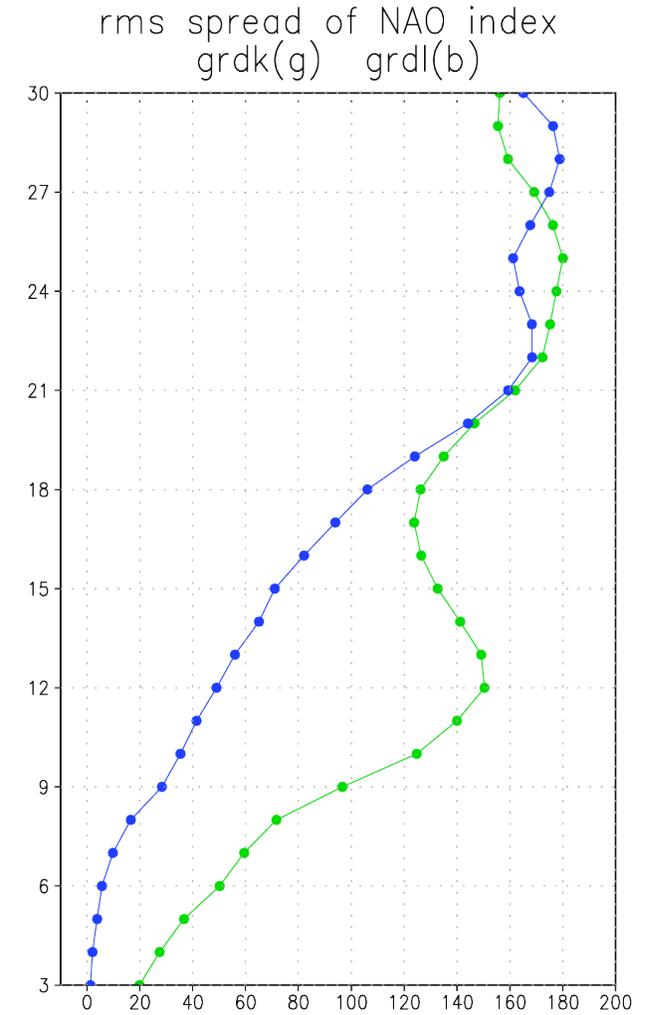

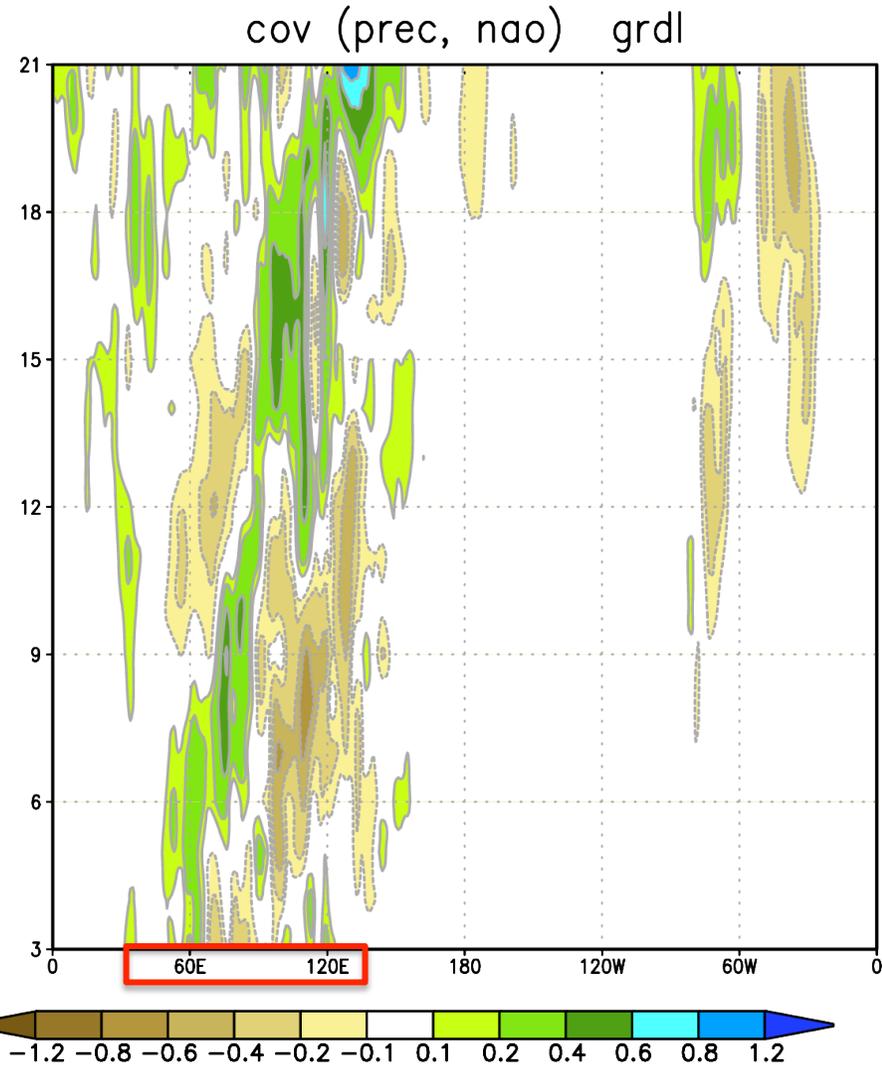

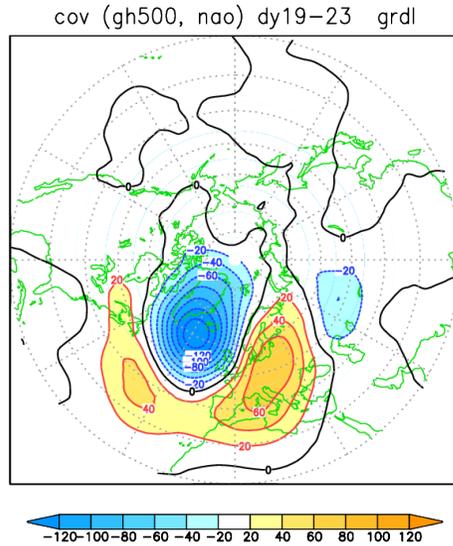

1. SPPT applied over the whole globe
2. SPPT only over tropical Indian Ocean – Maritime Continents (35-145E, 15N-15S)
3. SPPT only over tropical South America – Atlantic Ocean (90W-0, 15N-15S)

## PRIMAVERA: a European Union Horizon-2020 project ([www.primavera-h2020.eu](http://www.primavera-h2020.eu))

*Main goal: To develop a new generation of advanced and well-evaluated high-resolution global climate models, capable of simulating and predicting regional climate with unprecedented fidelity*

Motivation for ECMWF: to explore the climatological attractor of the ECMWF Earth System model (mean state and variability) in a state of near-equilibrium (as opposed to the transient, drifting state experienced during sub-seasonal and seasonal forecasts)

ECMWF contribution based on multi-decadal historical runs (as in CMIP6 HighResMIP) with:

- IFS Tco199 L91 + NEMO 1.0° Z75 + LIM-2
- IFS Tco399 L91 + NEMO 0.25° Z75 + LIM-2

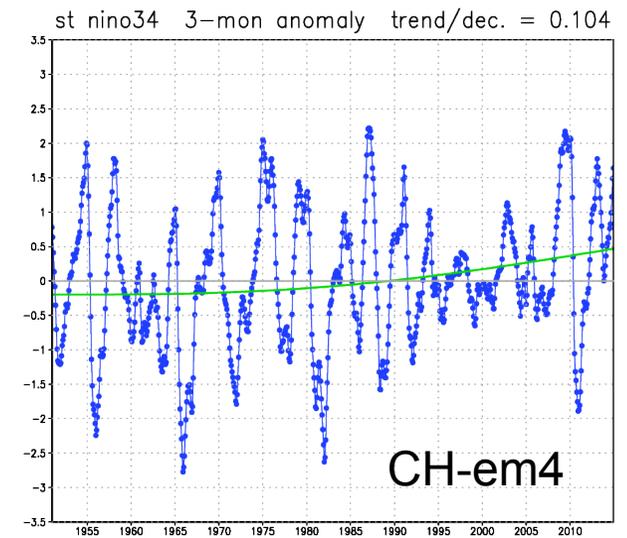

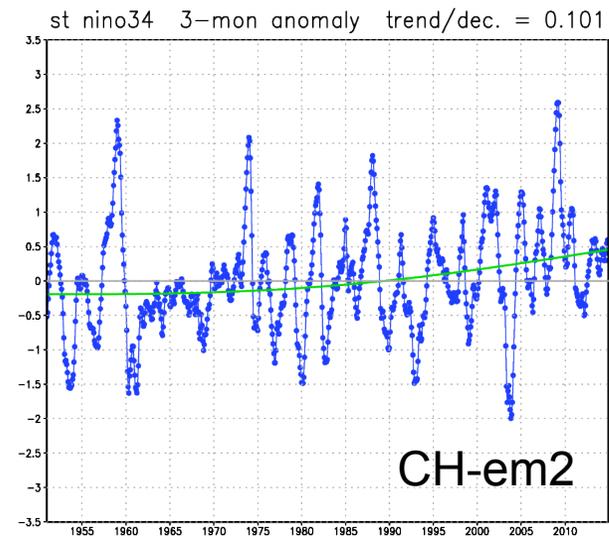

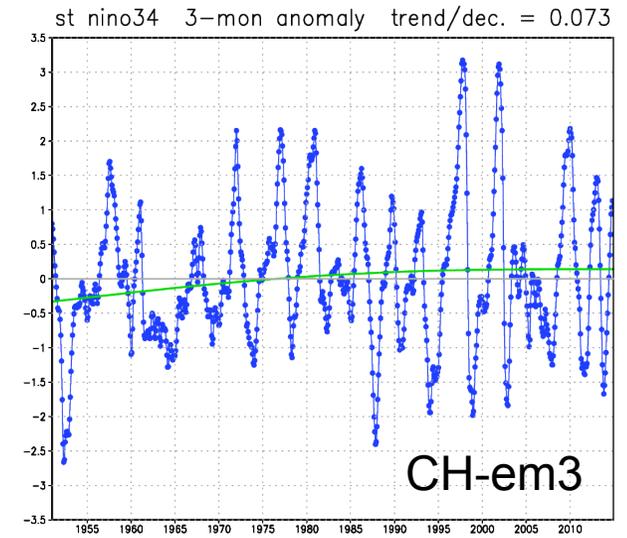

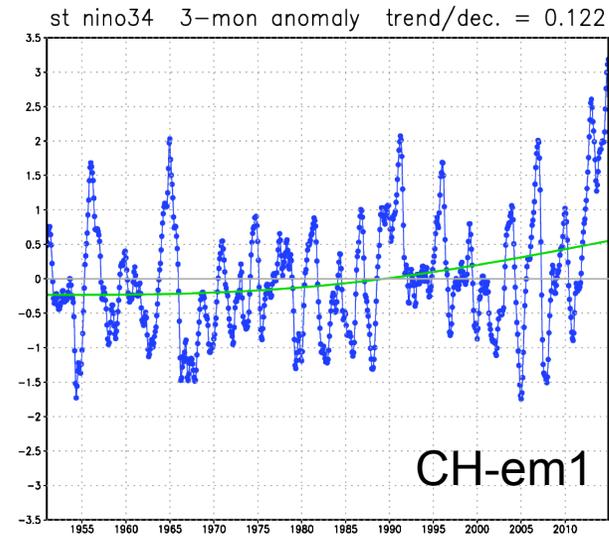

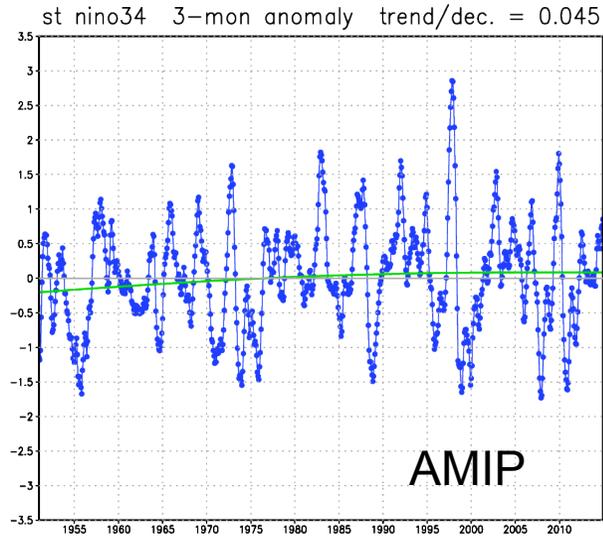

**WP2:** Provide a systematic assessment of the benefits of simultaneously increased atmospheric and oceanic resolutions and increased atmospheric resolution only in global coupled climate models for processes affecting European climate and its variability

**WP3:** Quantify the need for improved representation or levels of complexity of a range of physical processes within the atmosphere, ocean, land and sea ice in a high resolution environment

**WP4:** Develop the next generation of coupled models by testing different approaches to the representation of sub-gridscale processes and exploring the benefits of explicit representation at very high resolution

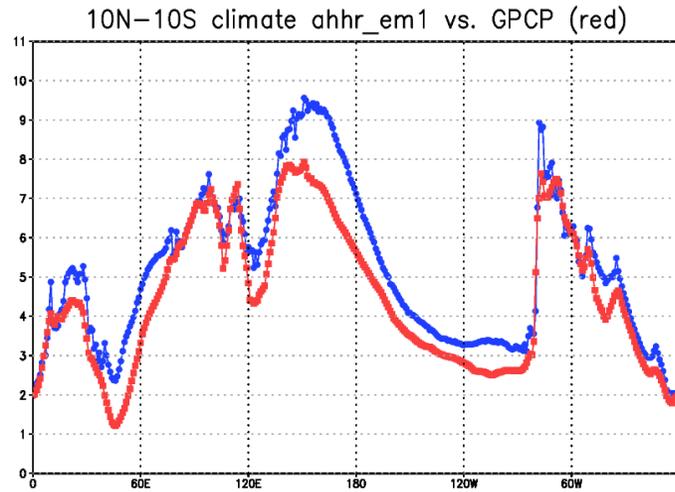

**WP5:** Improve understanding of the key oceanic physical and dynamical drivers and mechanisms leading to decadal variability of European climate, and assess the influences of regional climate phenomena such as the summer Arctic sea ice decline and Siberian snow cover reduction.

# Conclusions

- The teleconnection pattern associated with rainfall variability in the tropical Indian Ocean and the Maritime Continent can be reproduced in sub-seasonal ensemble experiments by stochastically perturbing the tendencies produced by physical parametrizations in the Indo-Pacific in cases in active MJO. The maximum NAO variability is reached about two weeks after anomalous heating is established in the western Indian Ocean.
- Multi-decadal runs with historical CMIP forcings for 1950-2014, run with the coupled ECMWF model (IFS-NEMO) for the PRIMAVERA project, show a realistic simulation of ENSO variability and the associated teleconnections, but on sub-seasonal scale convective activity in the Indo-Pacific does not show a coherent propagation. This strongly weakens teleconnections associated with Indian Ocean rainfall anomalies. On the other hand, in AMIP runs the absence of coupling increases the persistence of MJO-like heating anomalies, and stronger teleconnections are detected in the northern extratropics.
- On the seasonal time-scales, teleconnections from the Indian Ocean in both AMIP and coupled runs are also affected by an excessively strong correlation between western Indian Ocean rainfall and SST anomalies induced by ENSO in the central and east Pacific.
