Li-ion Battery Global Market

Research and Markets, Li-ion Battery Outlook (2018)

Battery Technology

- Li-ion acceptable for small electronic devices
- Does not meet long-term performance EVs

Thackeray *et al.*, Energy Environ. Sci., 2012, 5, 7854

TeamViewer.com

1M-LiTFSI/DME

Li metal reactivity:
 AIMD simulations
 show anion reduction
 due to electron transfer
 from the surface

first principles calculations

- **Methods of computational surface science/electrochemistry:**
 - DFT, high level ab initio methods
 - DFT-MD
 - DFT-MD + free energy calculations
- **Effect of electrode potential**

Electrochemical stability

Condition: $eV_{oc} \leq E_g$

Otherwise:
electron
transfer from
electrode to
electrolyte (or
vice versa)
may occur

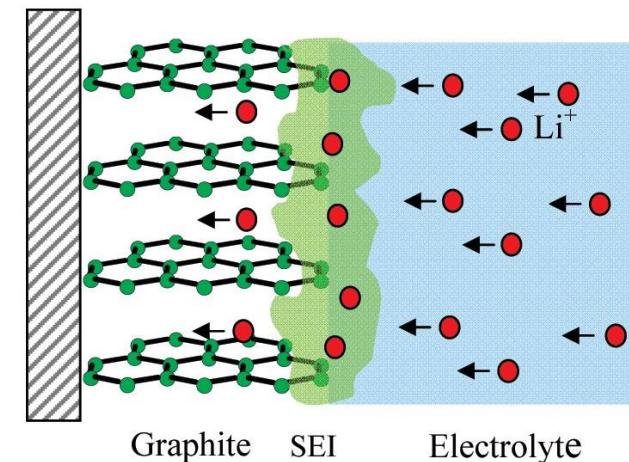

Materials design is crucial

**First-principles computational
analyses --
understand and predict complex
phenomena**

Solid-Electrolyte-Interphase layer

- SEI--surface film formed at anode and cathode surfaces

- Due to electrolyte decomposition (reduction or oxidation)

- May protect and stabilize anodes (carbon, Li metal); be unstable (metal-oxide cathodes; silicon anodes)

SEI "mosaic" composition

yes, there are other interfaces in life... any similarity is pure coincidence !!

Verma, Maire, Novak, EC Acta 2010

Thickness: from a few Å to tens or hundreds of Å

**How is the SEI layer formed
at the anode/electrolyte
interface?**

**Electrolyte:
solvent (cyclic and linear
carbonates)
+ salt (e.g. LiPF_6)
+ additives**

EC reductive dissociation

Wang, Nakamura, Ue, Balbuena, JACS, 123, 11708-11718, (2001)

Li⁺(EC) reductive dissociation

Much easier !!!
Li ions facilitate the reaction

Ion-pair intermediate;
e⁻ is transferred to EC

Radical anion

Termination reactions

lithium organic salt with an ester group

lithium butylene dicarbonate

Li-carbide

lithium ethylene dicarbonate + C₂H₂

insoluble inorganic Lithium carbonate

Another e⁻ transfer

SEI on carbons for different electrolyte compositions

Improving the anode capacity: The Si electrode (capacity: one order of magnitude > carbon)

SEI layer formation

Nano Today, Volume 7, Issue 5, October 2012, 414-429

Voltage range (relative to Li/Li⁺)

0.8 to ~0.4 V → ~0.2 V

LiSi₁₅

LiSi₄

LiSi₂

LiSi

Li₁₃Si₄

Early stages of lithiation

Highly lithiated

Extent of lithiation: Effect on EC reduction mechanisms

Very low lithiation

Li over the surface plane; Si-O_E bonds formed

1 and 2-e⁻ mech. can coexist based on calculated activation energies

Ma and Balbuena
JES, 2014

Intermediate to high lithiation

Li on the surface plane or in the subsurface: Si-C bonds are formed

2-e⁻ mech. preferred; at higher lithiation 4 e⁻ mech. observed

JM Martinez de la Hoz, K Leung and P B Balbuena, ACS Appl. Mat. and Interfaces, 2013

VC reduction on lithiated Si anodes

All surfaces

a) Li-O interaction

b) Formation of C-Si bond

c) Ring opening (open VC^{2-})

d) Cleavage of a 2nd C1O2 bond

} Higher lithiated

CO_3^{2-} is a product of EC and oligomers decomposition
(alternative mechanism to Ushirogata et al, JACS 2013)

VC products: open VC^{2-} , $\text{OC}_2\text{H}_2\text{O}^{2-}$, $\text{OC}_2\text{H}_2\text{OCO}_2^{2-}$, CO, CO_2

C=C containing species

Effect of degree of lithiation on additives

very low lithiation

FEC: 2 e⁻ mechanism preferred;
C_C-O_E and C_C-F bond cleavages:
low/moderate barriers

Ma and Balbuena
JES, 2014

multi-electron
reactions
on **highly lithiated**
surfaces

2 e⁻ transfer
to FEC → ring opening

C-F bond breaking

FEC can yield open VC anion
(path III) **and therefore all VC-**
derived products ,
in addition to other specific FEC
products (paths I, II, and III)

·OCOC₂H₂O²⁻, CO₂²⁻, H, F⁻

J. M. Martinez de la Hoz and P. B. Balbuena, PCCP, 16, 17091-17098 (2014)

Effects of electrolyte composition

Mixture	Number of molecules					% wt.
	EC	VC	FEC	DEC	LiPF ₆	
1	13	0	0	0	1	100 (EC)
2	12	1	0	0	1	7.5 (VC)
3	11	2	0	0	1	15 (VC)
4	7	6	0	0	1	46 (VC)
5	12	0	1	0	1	9.1 (FEC)
6	11	0	2	0	1	18 (FEC)
7	7	0	6	0	1	50 (FEC)
8	2	0	0	7	1	71.6 (DEC)

AIMD simulations of mixtures of various compositions

Salt produces LiF and other fragments interact with solvent products

Illustration:

mixture 3
15% wt VC

How is the ionic/electronic transport through the various SEI components:

- LiF (from salt or solvent)
Li₂O (from further reactions among products), Li₂CO₃,
organic oligomers, polymers??
- How are “good” and “bad” SEI layers characterized?
- How does the SEI layer grow beyond the e⁻ tunneling regime?

Electron transfer through growing SEI

We examined oligomers:

Li₂EDC, Li₂VDC

+ OH[•]

0.0 kcal/mol

energy values in Kcal/mol

-21.7 kcal/mol

CO bond breaking

new radicals
are formed;
electron
transfer
shown by
blue regions

Attack of Li₂EDC by radical species debilitates its bonds causing fast decomposition. Same for Li₂VDC

SEI from VC/FEC (“good”) vs. EC (“bad”)

oligomers (formed from Li_2EDC , Li_2VDC and others) decompose by radical attack; generate more radicals → SEI uncontrolled growth

best additives
control excessive radical formation

**surface structure and
electrolyte chemistry play important roles;**

how does the surface chemistry matter?

- native oxides**
- artificial coating**

SiO₂ : lithiation and reactivity

hydroxylated amorphous Si surface

Lithiation formation energy

$$\Delta E(x) = [E(\text{Li}_x\text{Surface}) - x E(\text{Li}_{\text{metallic}}) - E(\text{Surface})] / N$$

Structural evolution

Lithiation mechanisms in native oxides

Si-O broken, Si-Si formed, Li₆O complexes formed

hydroxylated amorphous film $\text{Li}_x\text{SiO}_{2.48}\text{H}_{0.97}$

$x = 0.37$

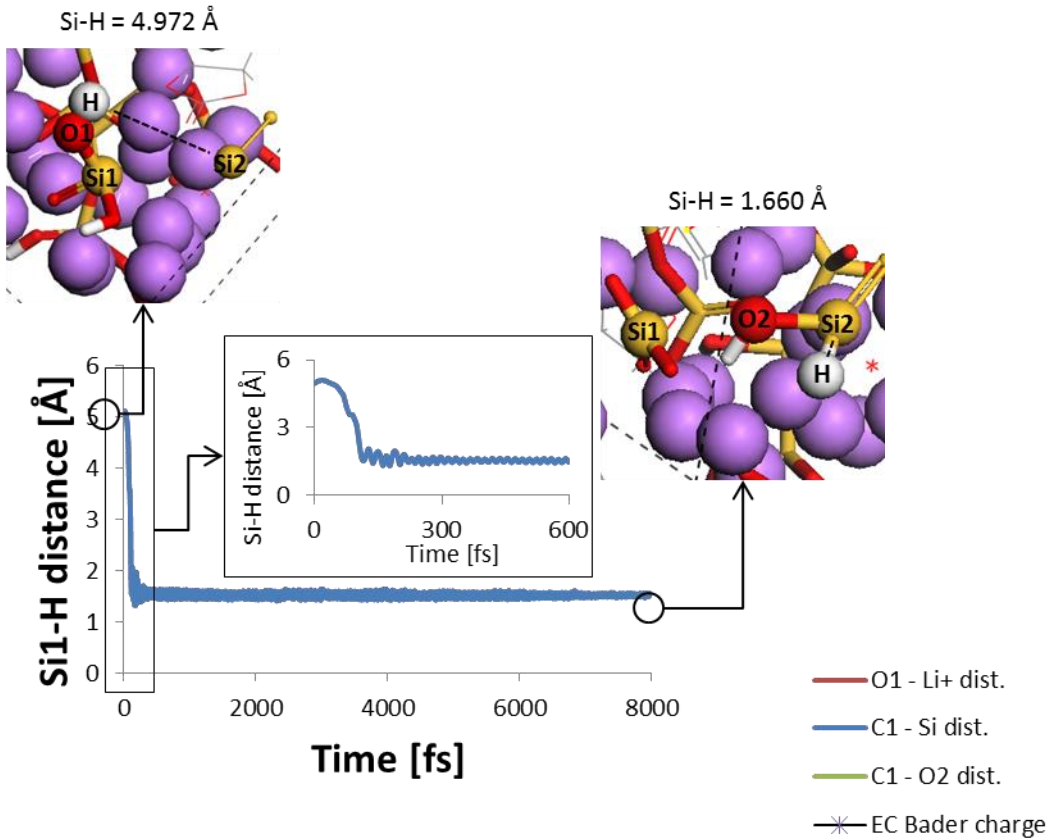

$x = 1.48$

$x = 3.33$

Lower reactivity of the hydroxylated surface

decomposition of OH groups and formation of SiH bonds

2 e⁻ reduction of EC

Aluminum alcoxide (alucone) coating

- Collaboration with Chunmei Ban (NREL)

film formation, lithiation, reactivity

Film lithiation

-2.63 eV; -3.15 eV; -3.3 eV

**agreement with
experiment:
fast film lithiation**

**binding to
the film stronger
than to Si**

Electronic conductivity in alucone film

once the film is saturated with Li,
it becomes electronically conductive;
SEI reactions observed

Collaboration
with C. Ban (NREL)

what type of SEI layer could be formed over alucone-covered Si?

inside the film
 or at the
 interface

2 e⁻ reduction of EC at the alucone/electrolyte interface

Gomez-Ballesteros and Balbuena,
JPC Lett 2017

Artificial layer modified & covered by a natural SEI

- Solvent and its decomposition products able to penetrate the film
- The alucone film is modified because SEI decomposition products form complexes with AlO_x groups inside the film or at the interfaces
- Reactions may take place at the film/electrolyte interface or at the anode/film interface

Li metal issues:

extremely high reactivity → **uncontrolled electrodeposition and dendritic growth**

Most strategies are based on:

- a) mechanically stopping or reducing the growing dendrite structure (solid electrolytes, coatings);
- b) reducing the ionic current (high salt concentration)

It is crucial to understand,

- Is there a **chemical origin of the dendrite growth?**
- How does the surrounding **environment modify the intrinsic Li reactivity?**

Understanding charge transfer from the surface

Solvent + salt $\text{Li}^+ \text{PF}_6^-$ on Li-metal surface

large charge transfer
from the surface to EC (-1.84 e) in
presence of a Li ion; EC is reduced;
 Li^+ is not reduced (+0.87 e)

solvent electron affinities and
solvation properties **decide** whether the
solvent or the Li ion are reduced

small charge transfer
from the surface to DME (-0.15 e) in
presence of a Li ion; DME is not reduced;
 Li^+ is reduced;
large electron accumulation on
the surface

yellow: e- accumulation
blue: e- depletion

Qin, Shao, Balbuena

Understanding Li plating: $\text{Li}^+ + \text{e}^- \rightarrow \text{Li}^0$

Li^+ reduced over a defect

a

b

c

yellow:
 e^- accumulation
light blue:
 e^- depletion

dark blue region:
cross-section of
charge density

Li^+ is reduced; large electron accumulation region near reduced Li:
It may attract and reduce further Li cations (needle growth) and electrolyte (SEI)

Understanding Li plating

Li_2CO_3 partially covered surface

a

b

top view showing e⁻ accumulation (yellow)

X. Qin, M. Zhao, and P. B. Balbuena, EC Acta, 2018

Li deposition generates an uneven distribution of charges near the reduction site; such large e⁻ accumulation can attract more Li cations → favoring further plating on localized regions instead of smooth deposition

Reactive force field

Samuel Bertolini

Basis of the AIMD/ESM method

Otani and Sugino, PRB 73, 115407 (2006)

Total energy functional

$$E[\rho] = T[\rho] + E_{\text{xc}}[\rho] + \frac{1}{2} \iint d\mathbf{r} d\mathbf{r}' \frac{\rho(\mathbf{r})\rho(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} + \int d\mathbf{r} v_{\text{ext}}(\mathbf{r})\rho(\mathbf{r}) + E_{\text{ion}}$$

$V \rightsquigarrow$ variable

$$E[\rho_e, V] = T[\rho_e] + E_{\text{xc}}[\rho_e] + \int d\mathbf{r} \left[+ \frac{\epsilon(\mathbf{r})}{8\pi} |\nabla V(\mathbf{r})|^2 + \rho_{\text{tot}}(\mathbf{r})V(\mathbf{r}) \right]$$

$$\frac{\delta E}{\delta V} = 0$$

Poisson equation

$$\nabla[\epsilon(\mathbf{r})\nabla]V(\mathbf{r}) = -4\pi\rho_{\text{tot}}(\mathbf{r})$$

conventional

$$\epsilon(\mathbf{r}) = 1$$

$$V(\mathbf{r}) = \int d\mathbf{r}' \frac{\rho_{\text{tot}}(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|}$$

$$\frac{\delta E}{\delta \rho_e} = 0$$

Kohn-Sham equation

$$\left[-\frac{1}{2}\nabla^2 + V(\mathbf{r}) + \hat{V}_{\text{NL}} + V_{\text{xc}}(\mathbf{r}) \right] \psi_i(\mathbf{r}) = \varepsilon_i \psi_i(\mathbf{r})$$

ESM

$\epsilon(\mathbf{r})$: model dependent

$$V(\mathbf{r}) = \int d\mathbf{r}' G(\mathbf{r}, \mathbf{r}') \rho_{\text{tot}}(\mathbf{r}')$$

Uses open boundary conditions in the direction perpendicular to the slab to avoid discontinuities of the electric field. $V(\mathbf{r})$ is solved analytically from Poisson equation and is used in the Kohn Sham formalism of DFT

Electrode/electrolyte interface

Simulation set as a slab in an electrochemical cell

Simulation set as a slab in a capacitor

Effects included in AIMD

- Ionic distribution
- Screening effect of electrolyte
- Interaction metal/electrolyte
- Electronic structure

*In addition, first principles molecular dynamics under a bias potential: **AIMD + ESM** (effective screening method) include:*

- Bias potential
- Electrical double layer

ESM method from Otani and Sugino, PRB, 73, 115407 (2006)

Effective screening medium method

Model system: Cu(001) surface and LiFSI molecule solvated in DME

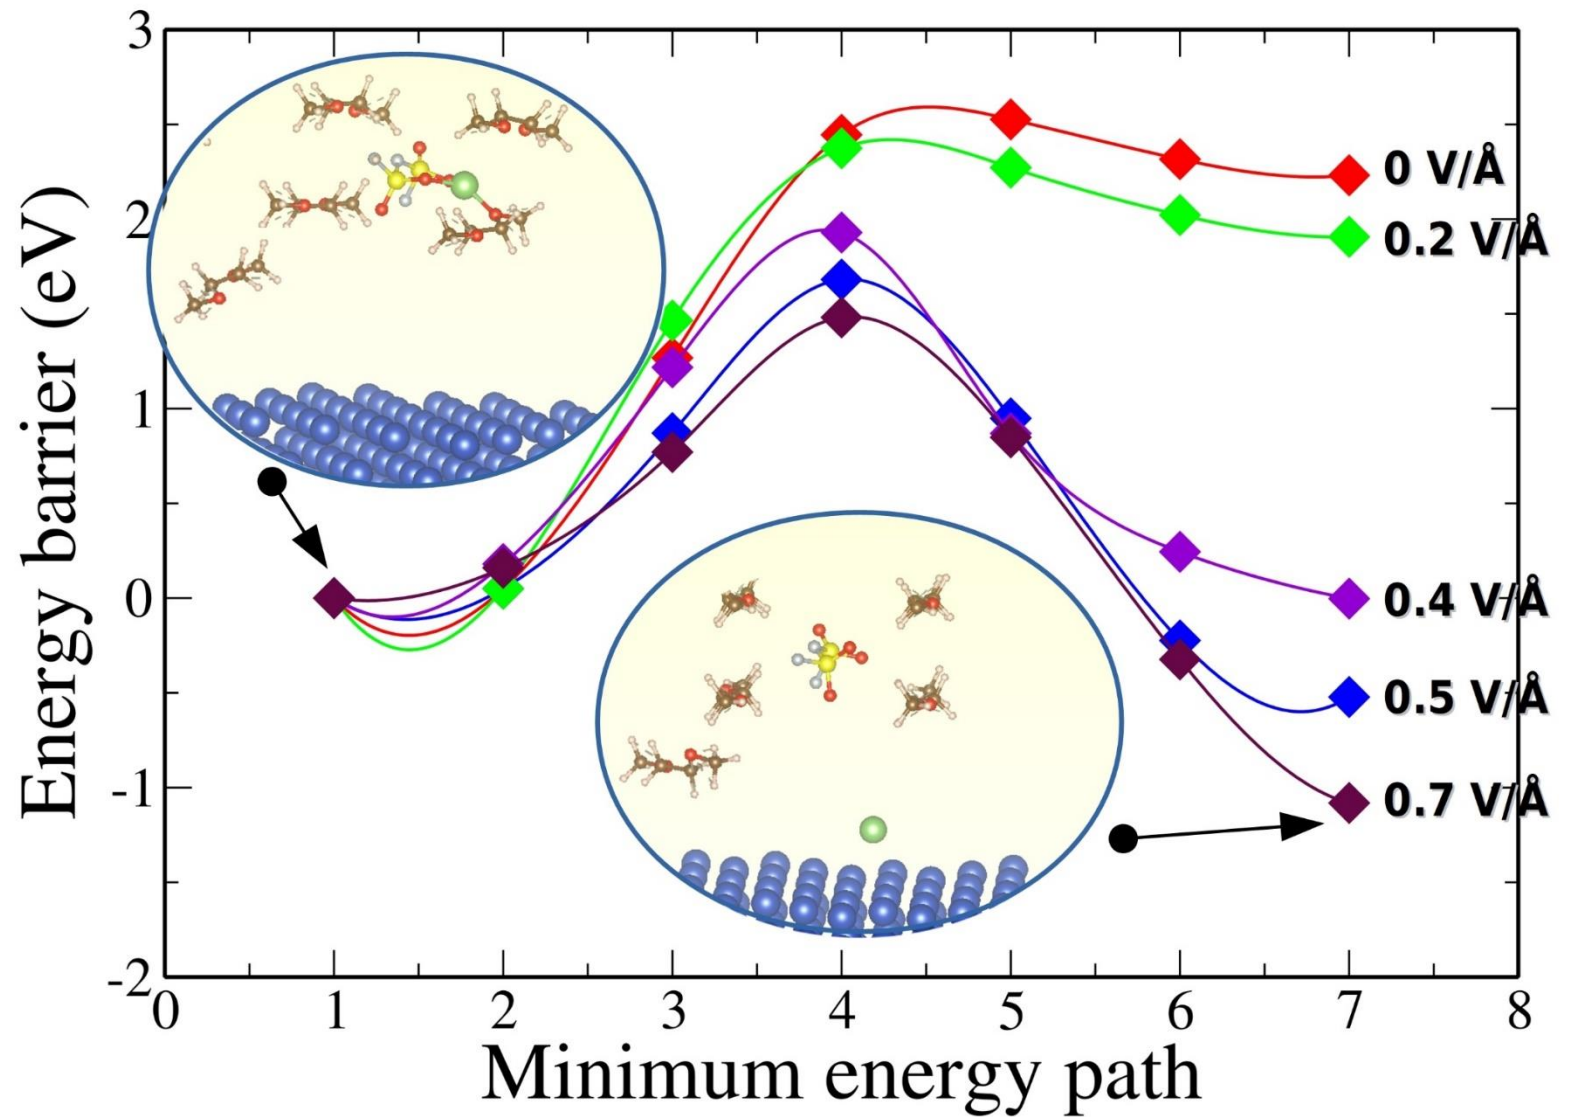

i) At $E=0$ V/Å, the deposition of a Li adatom is a highly endothermic process, $\Delta E=2.23$ eV

ii) In the presence of E , the surface is polarized. Can this trend be reverted? Is it a kinetically viable process?

Effects of applied potential

At $E=0.4 \text{ V/\AA}$, Li^+ deposition becomes exothermic, with a LiFSI dissociation energy barrier of 1.92 eV

Effective screening medium method

Even though Cu is a noble metal, the EF polarizes the surface, increasing the “capacity” of the Li ion to be reduced, i.e., the Fermi level “shifts” to the right

$E=0$ eV/Å

$E=0.5$ V/Å

Effective screening medium method

MD modeling of the Li deposition process, for $E=0.5 \text{ V/\AA}$ (electrodes not shown)

Effective screening medium method

After 7.5 ps of MD, a Li-DME composite adsorbed on Cu(001) is obtained:

i) The Li ion is only partially reduced: $\Delta q=0.37e^-$

ii) Cu is noble metal. As such, it is very resistant towards corrosion and oxidation

iii) Other substrates, like Li itself, would accelerate the reduction of the Li ion, at the cost of surface stability.

Li(001) surface polarization orbitals created by a $E=0.5 \text{ V/\AA}$. These orbitals do not exist for Cu(001).

Conclusions

- **Interfaces are very complex**
- **First principles methods help in the understanding of the complexity**
- **Understanding the physics and chemistry of the problem essential to decide on the computational model**
