## <sup>99</sup>Mo Production in 1MWt MSR

A dominant portion of present sources of Mo-99 is produced using high-enriched uranium targets irradiated in nuclear reactors and most of global supply relies on the operation of only five aging research reactors.

Among reactor methods of Mo-99 production, extracting radioisotopes from molten-salt fluoride fuel by fission is an attractive technology that has a great potential for large-scale production.

## MASS OF U-235 & ACTINIDES IN FUEL SALT

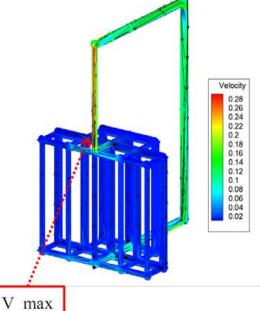

### **MO-99 PRODUCTION EFFECTIVNESS**

Mo-99 is a major radionuclide in fission products and 1 MW MSR potentially can produce a significant amount of Mo-99, approximately 1922 TBq in saturation. The special filters must be created and experimentally approved.

# Summary

- The molten salts have many desirable properties for mentioned above applications, and it seems likely that – given sufficient development time and money - a successful burner or breeder system could be developed
- Introduction of MSR technology to nuclear power might include 3 stages: FSCR, MSCR and MOSART
- It is obvious from the discussion above that use of molten fluorides as coolant and fuel for a reactor system of new fuel production or incinerator type operating in critical or fusion driven modes faces a large number of formidable problems. Several of these have been solved, and some seem to be well on the way to solution. But it is also clear that some still remain to be solved
- It may even be uncertain whether such a system would serve a useful purpose if its successful development were assured. It is certain that effort to date has thrown light on e. g. much elegant high temperature non-aqueous chemistry and has shown how molten salts can operate under hard and strong conditions
- Finally, it open perspectives significantly different to the present reactor and fuel cycle technology
