# F.H. Busse

Almost certainly the most versatile person in thermal convection

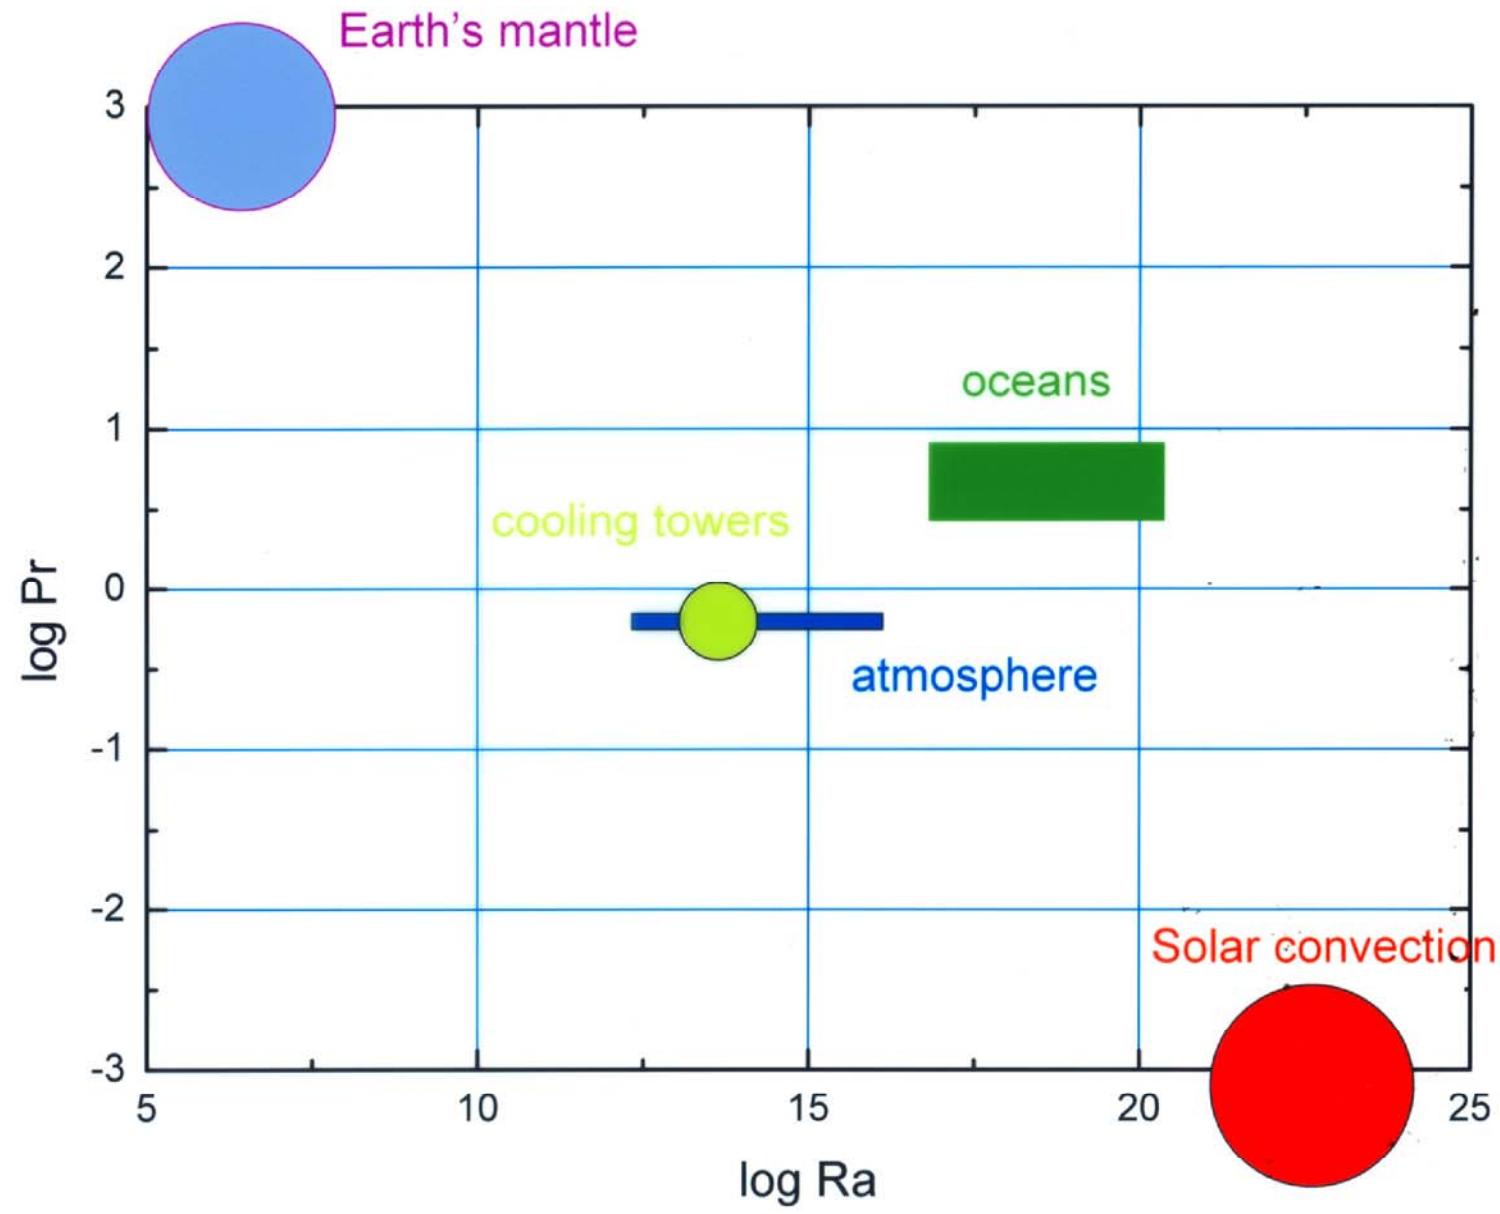

70 papers in *J. Fluid Mech.* dealing with convection

- Rotation
- Magnetic effects
- Prandtl number effects
- Geometry effects
- Phase changes
- Pattern formation
- Non-Boussinesq effects

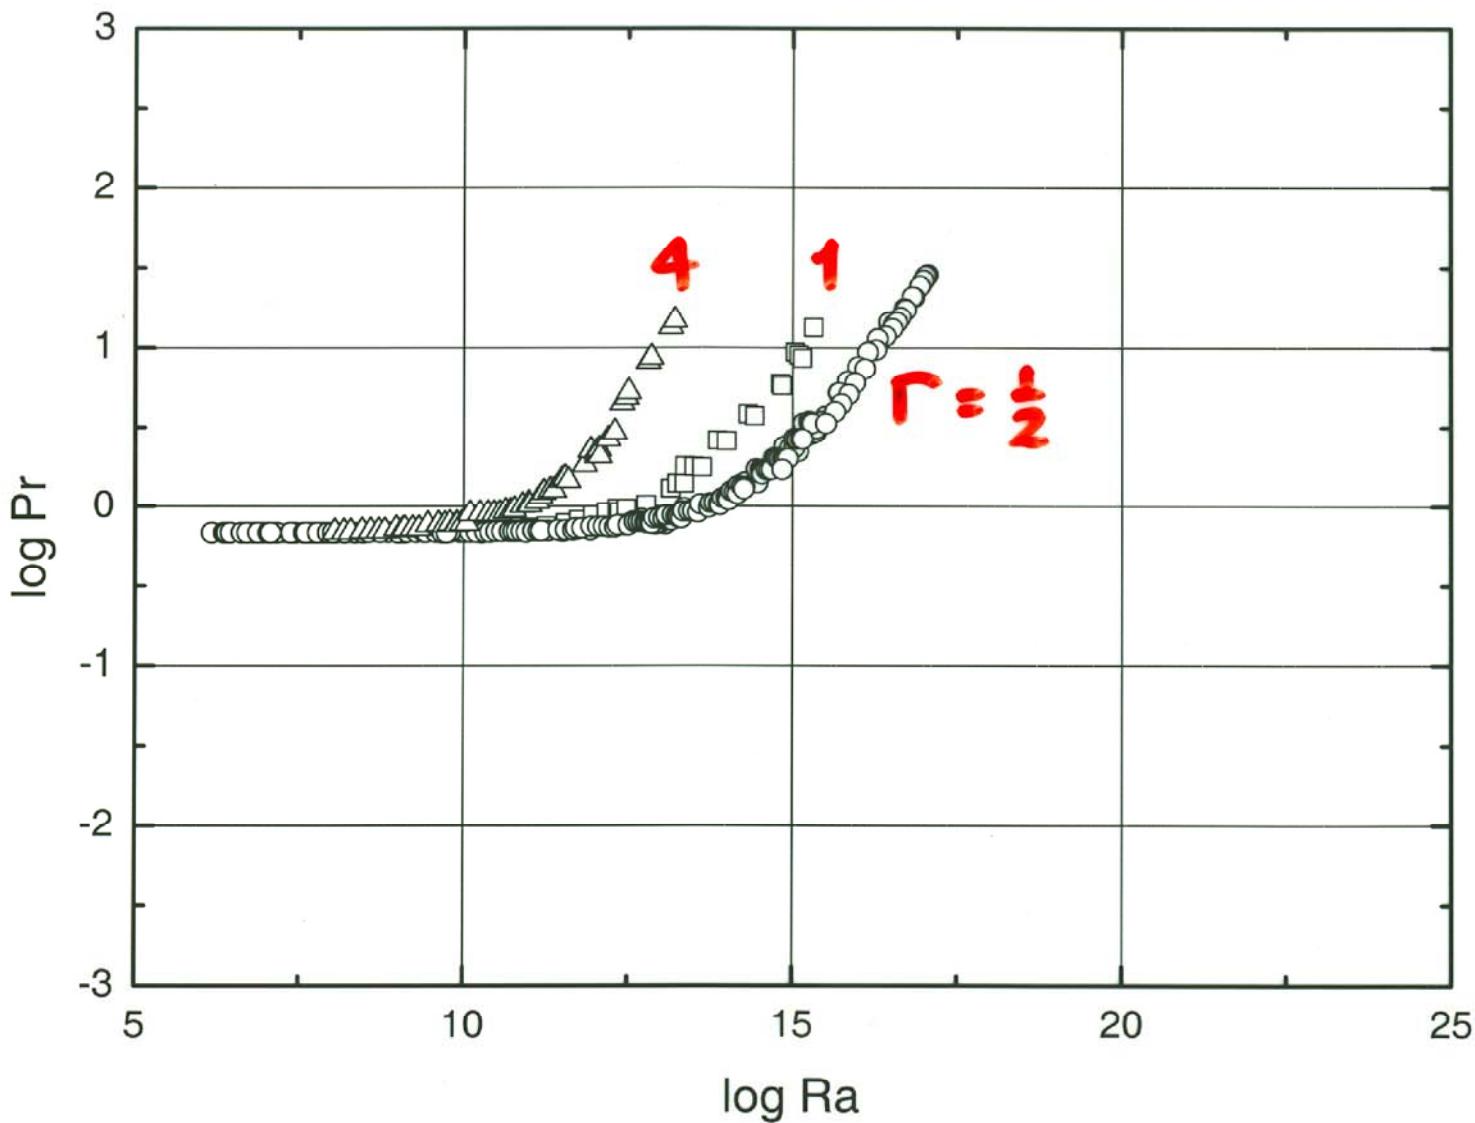

All are non-trivial papers.

## Ruminations on convection

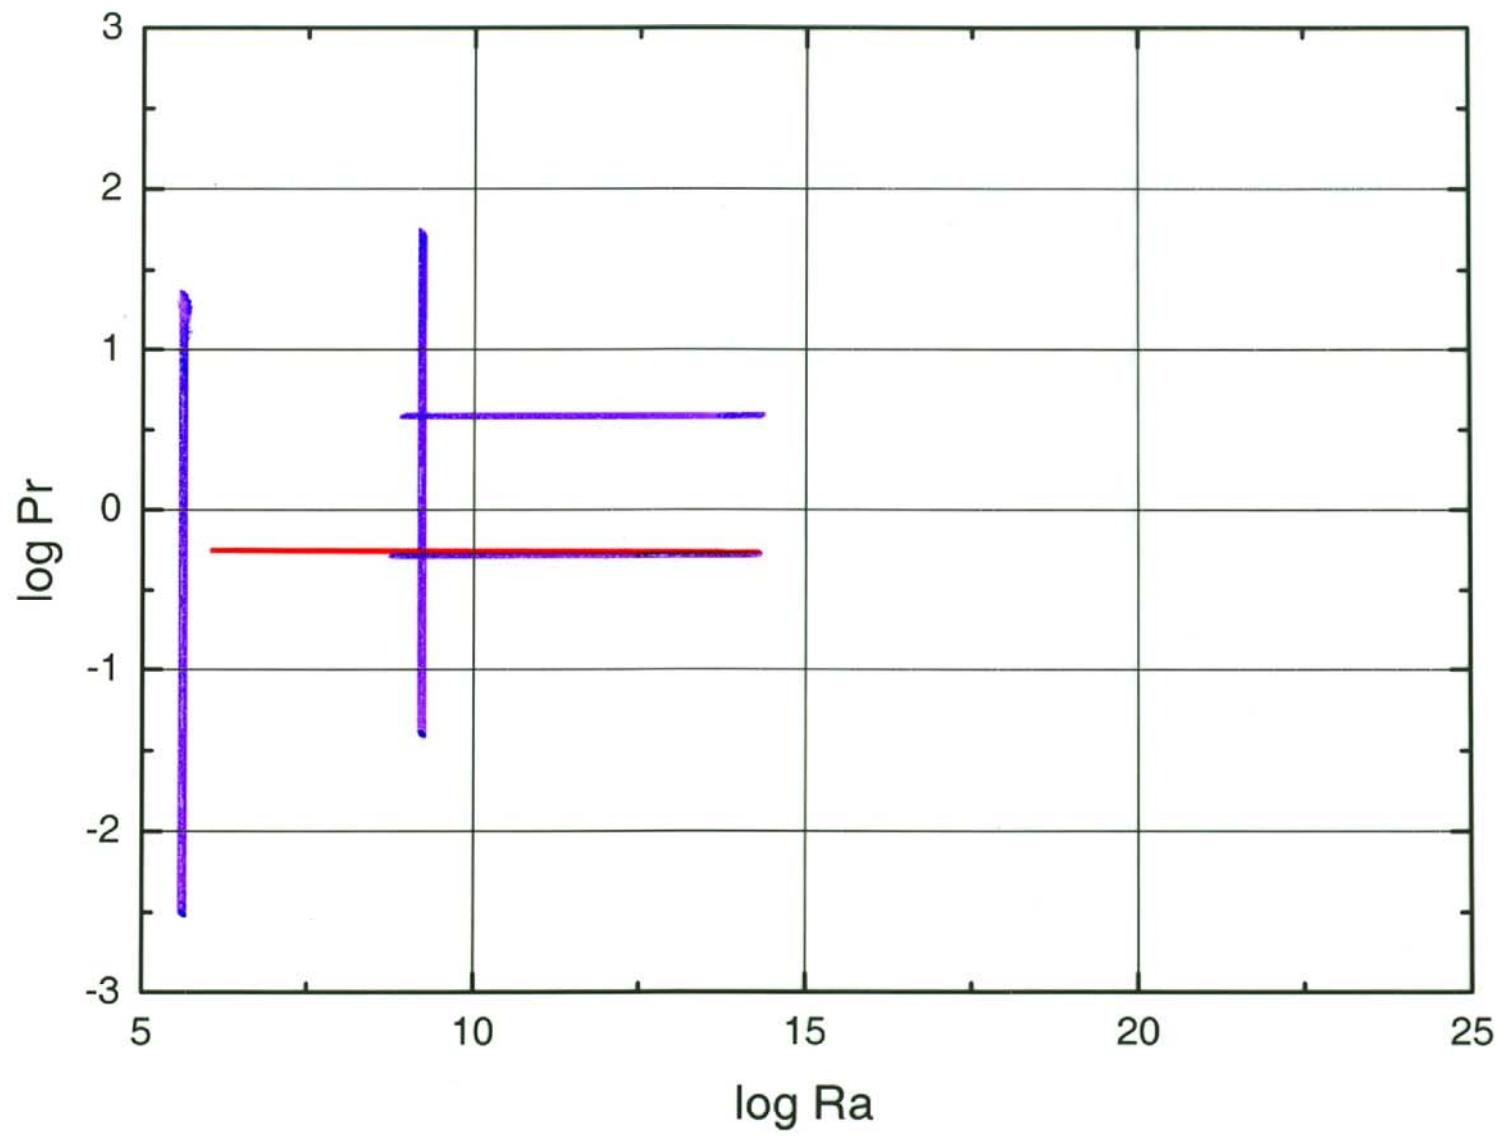

Ruminate = chew again what has been  
chewed slightly and swallowed

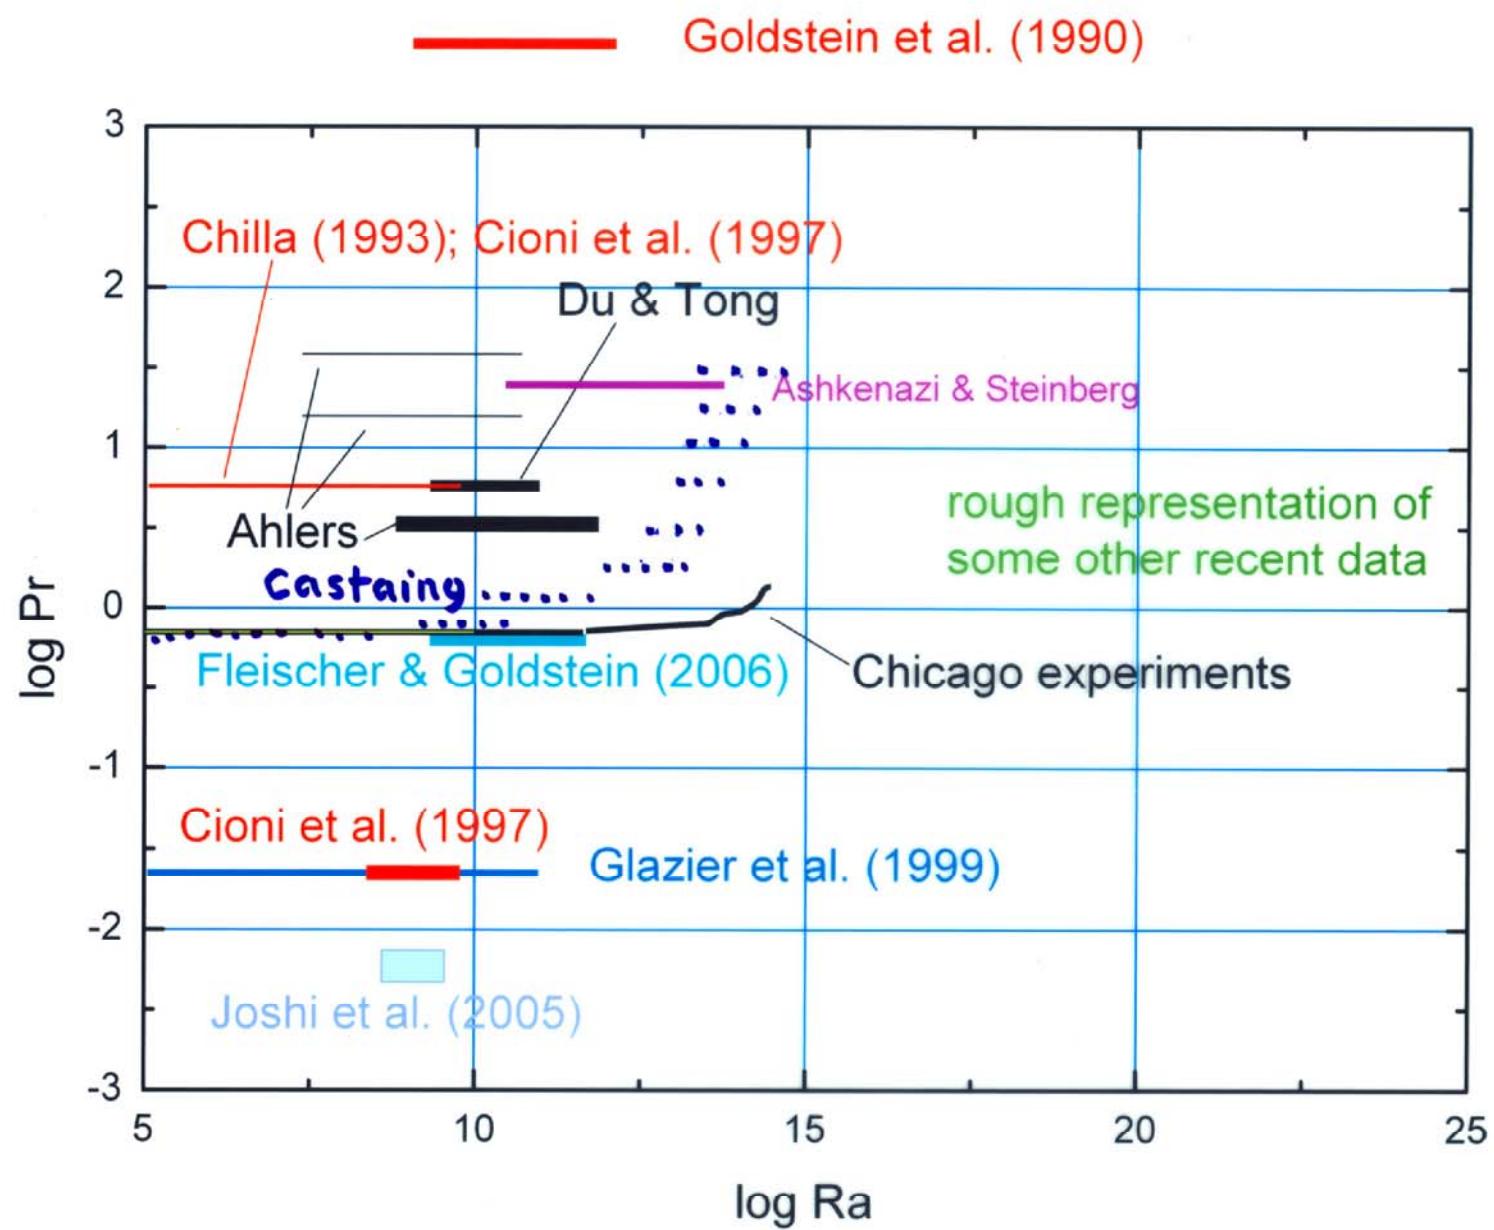

**SOME PARADIGMS OF CONVECTION**

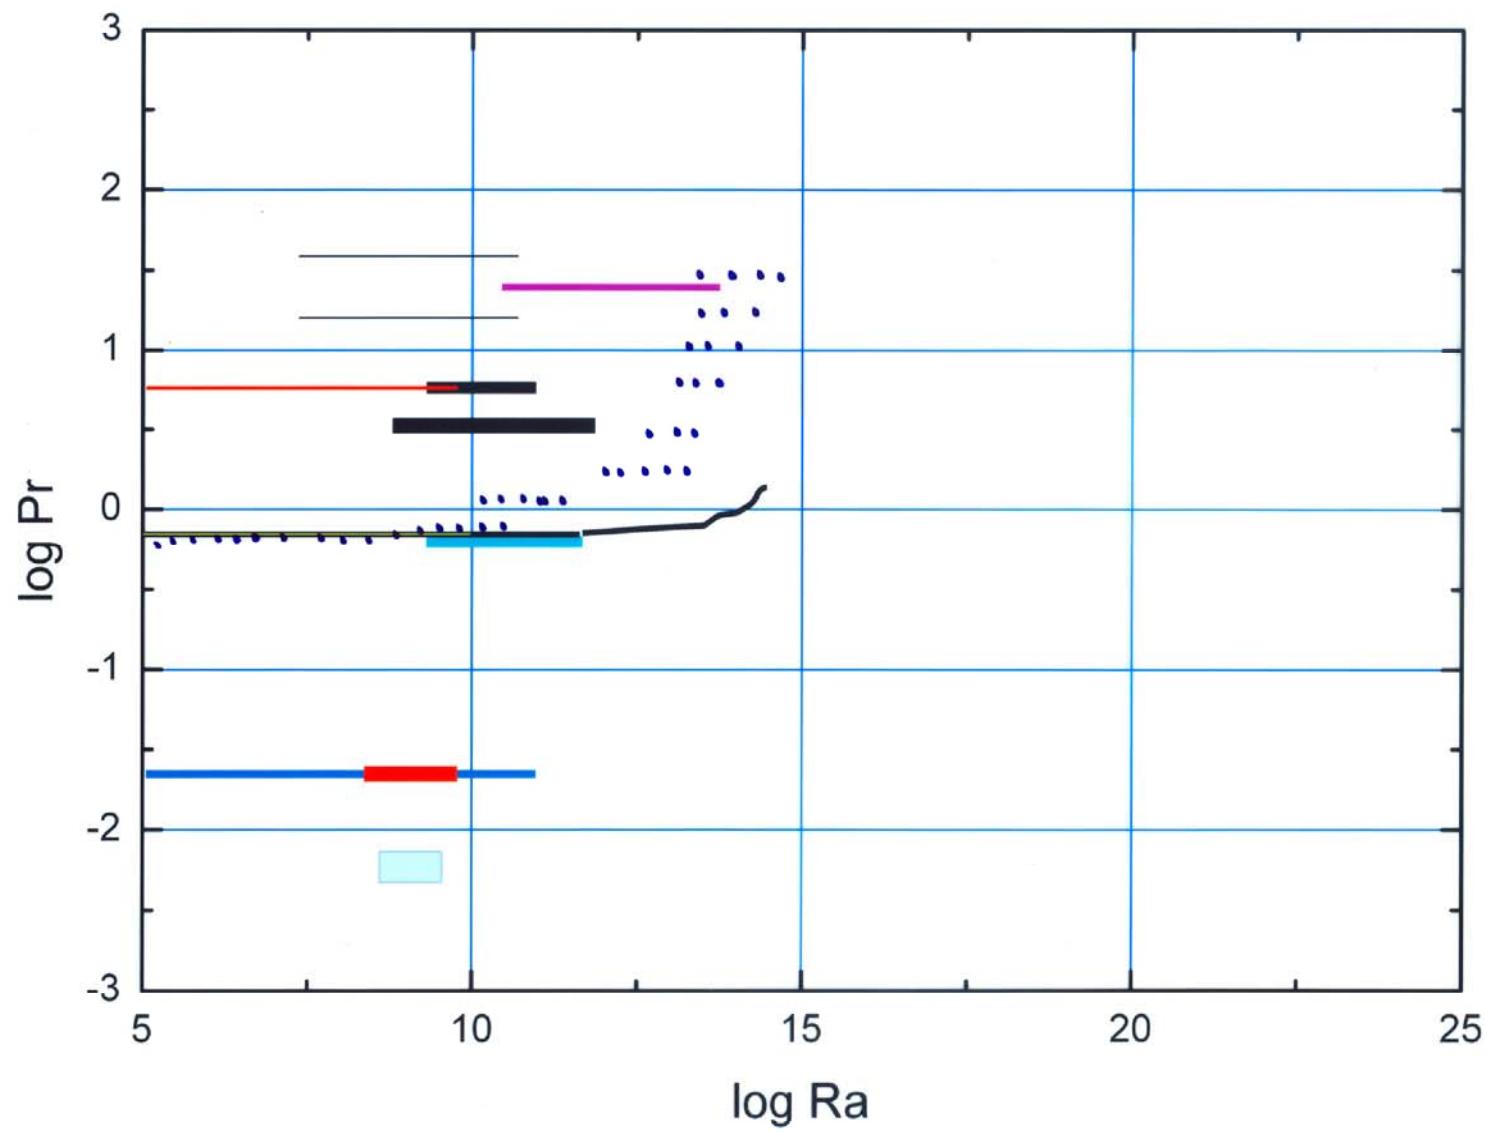

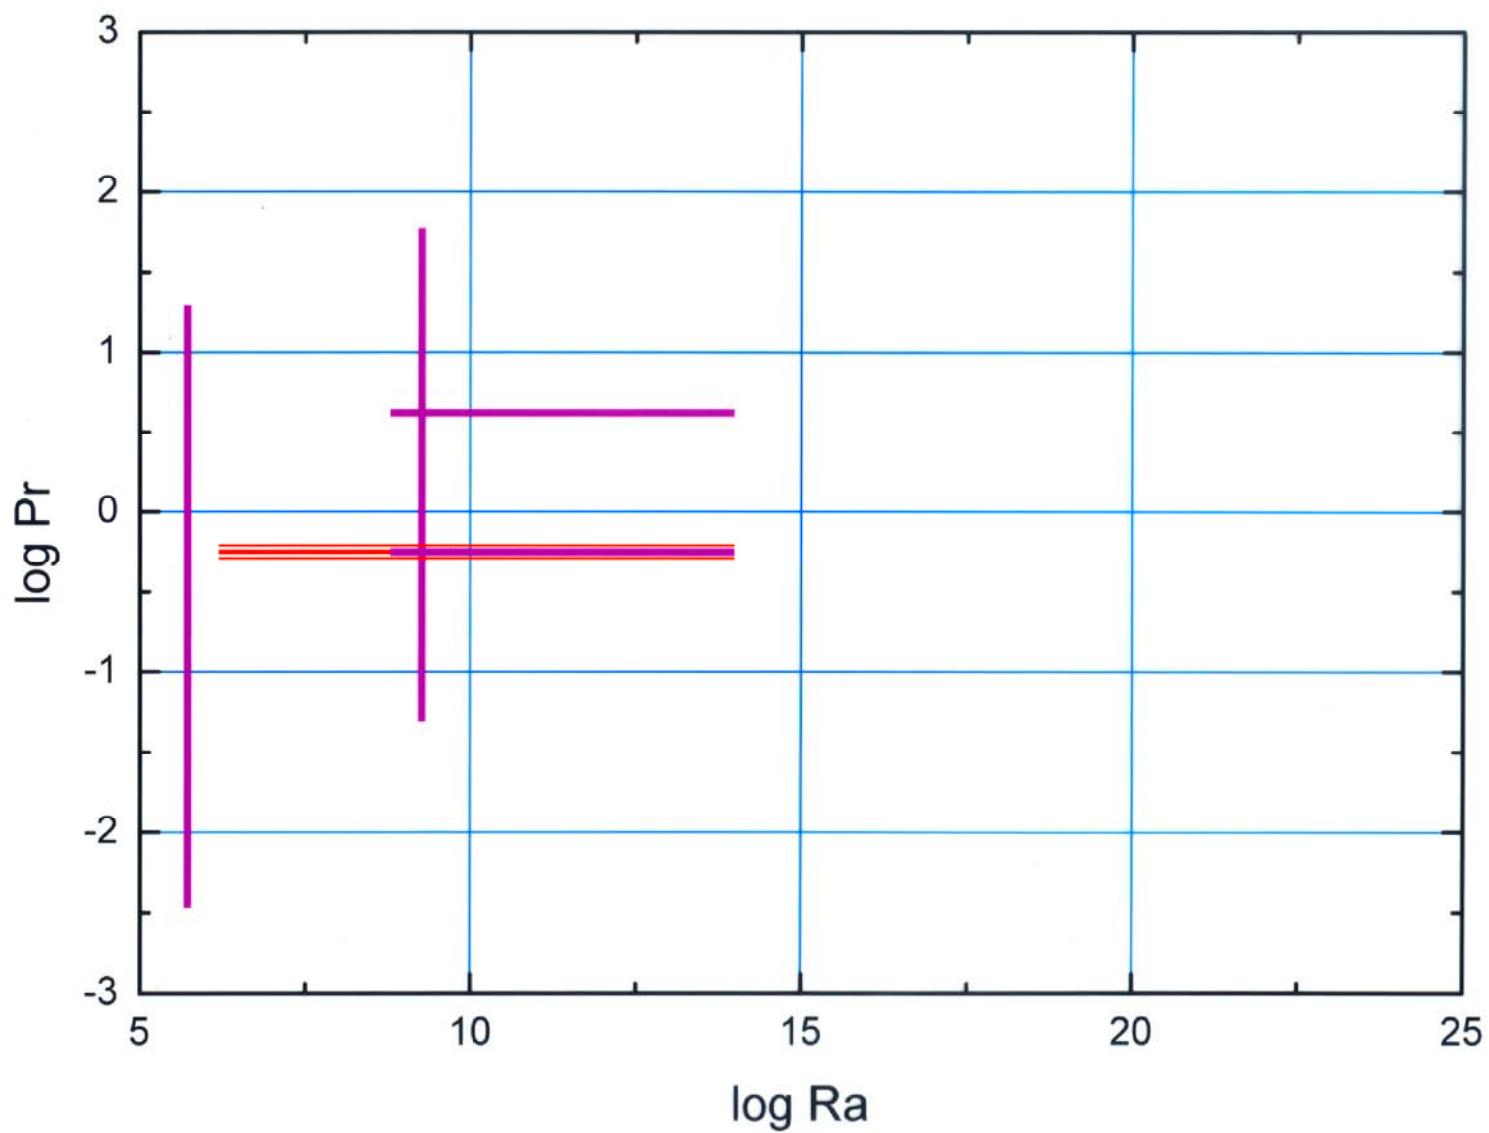

Experiments with J.J. Niemeier ...

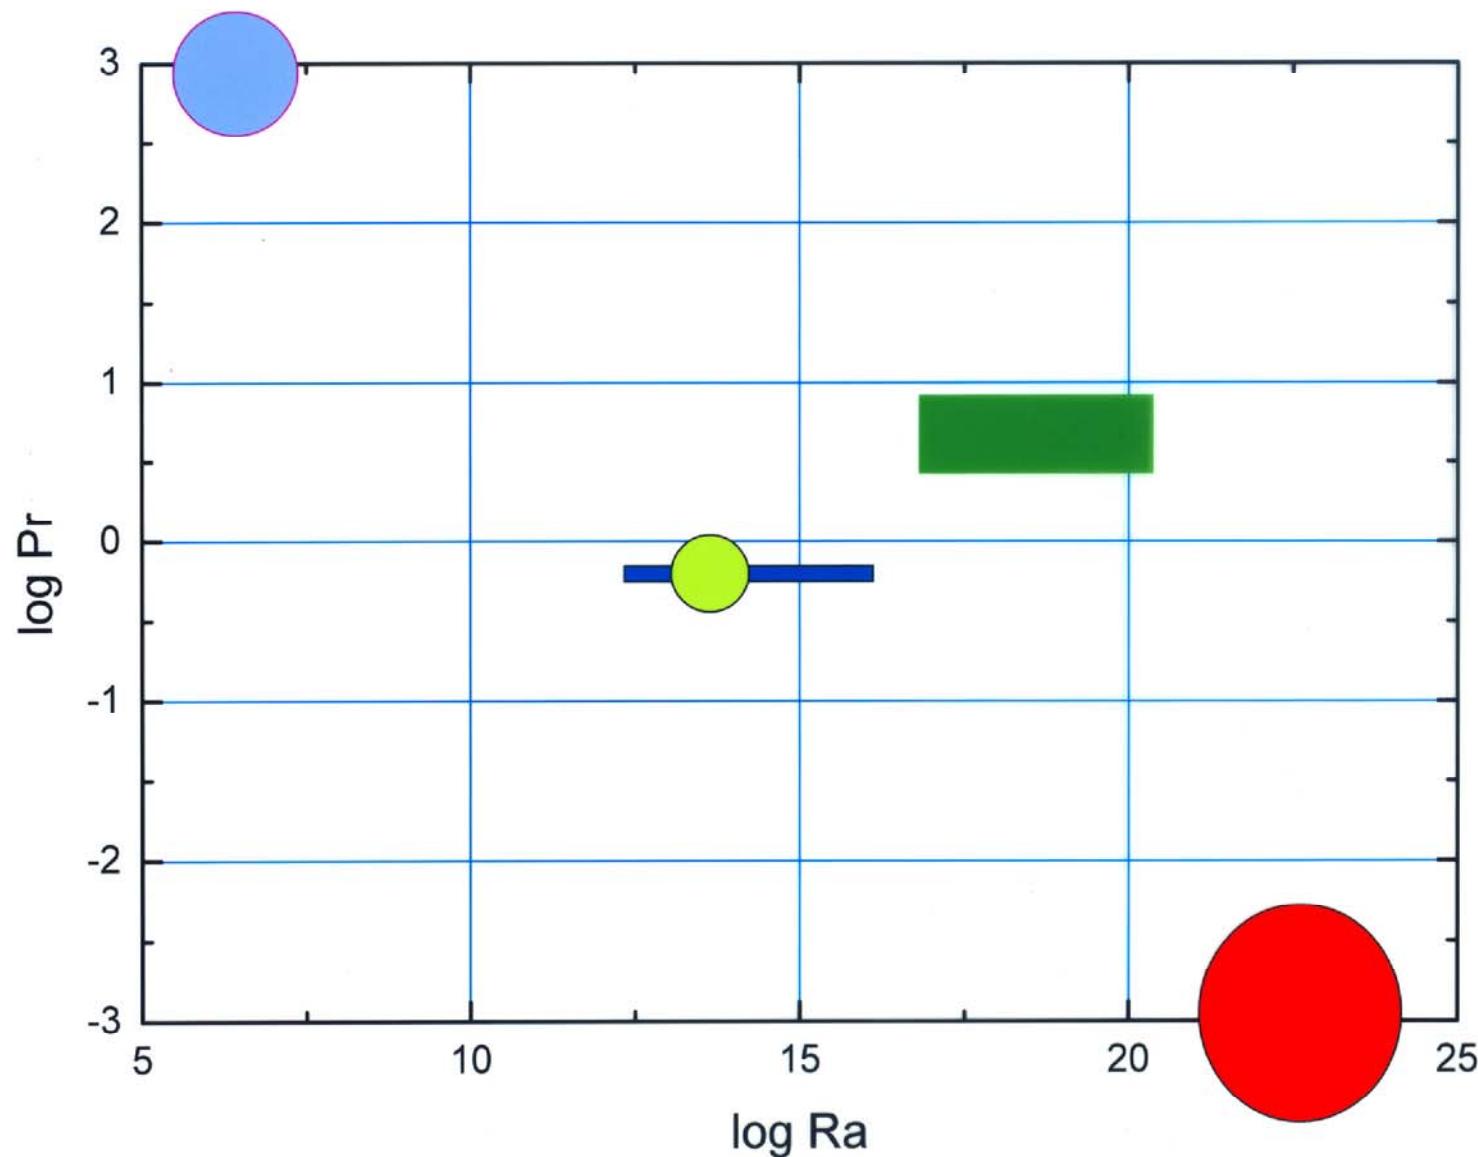

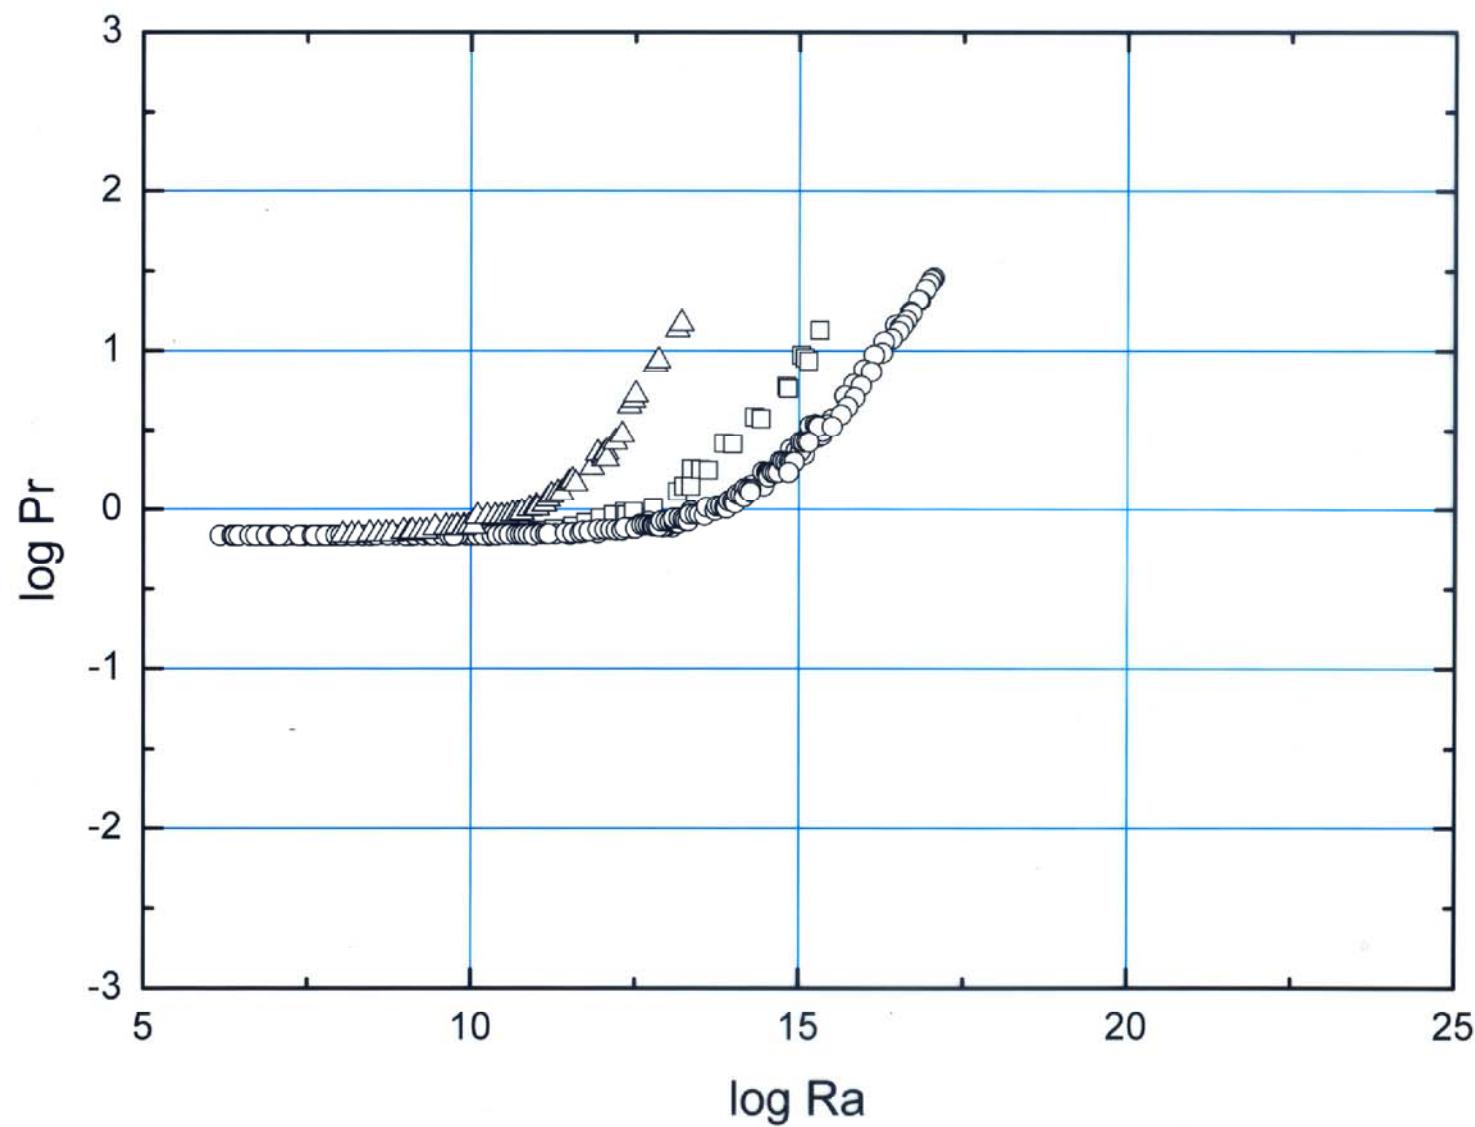

VERZICCO'S SIMULATIONS

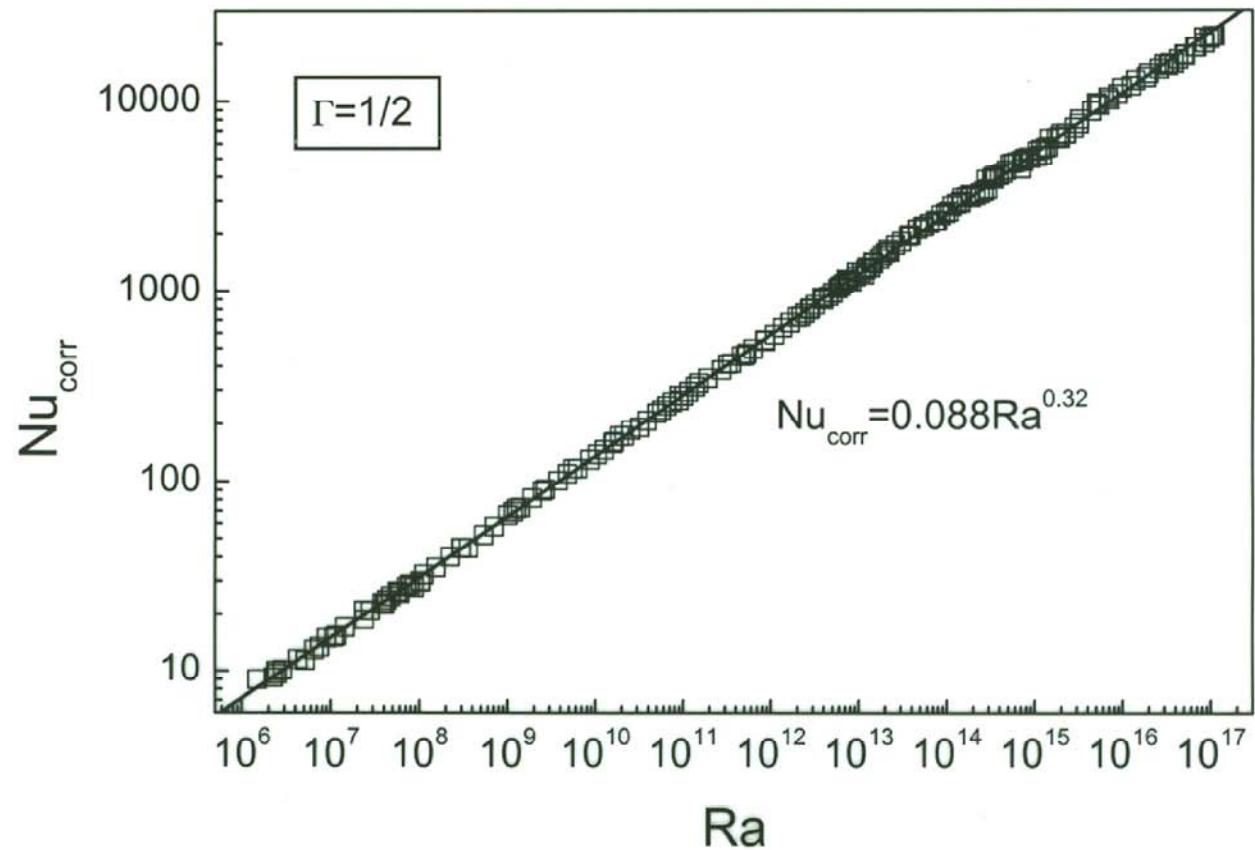

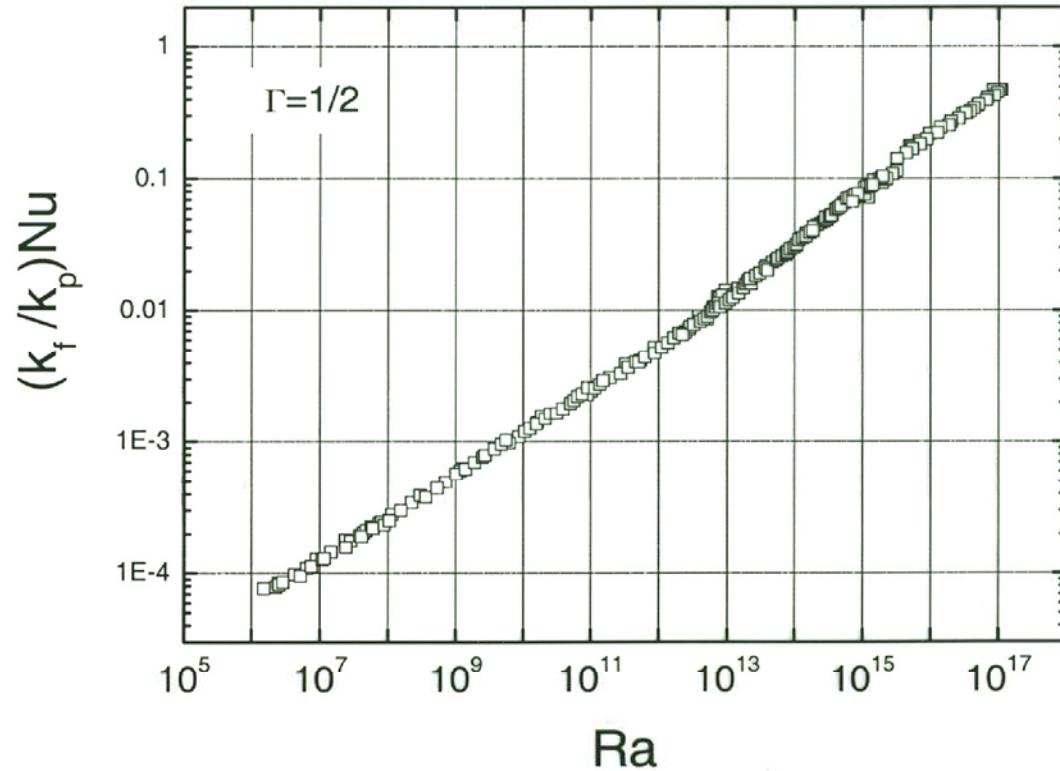

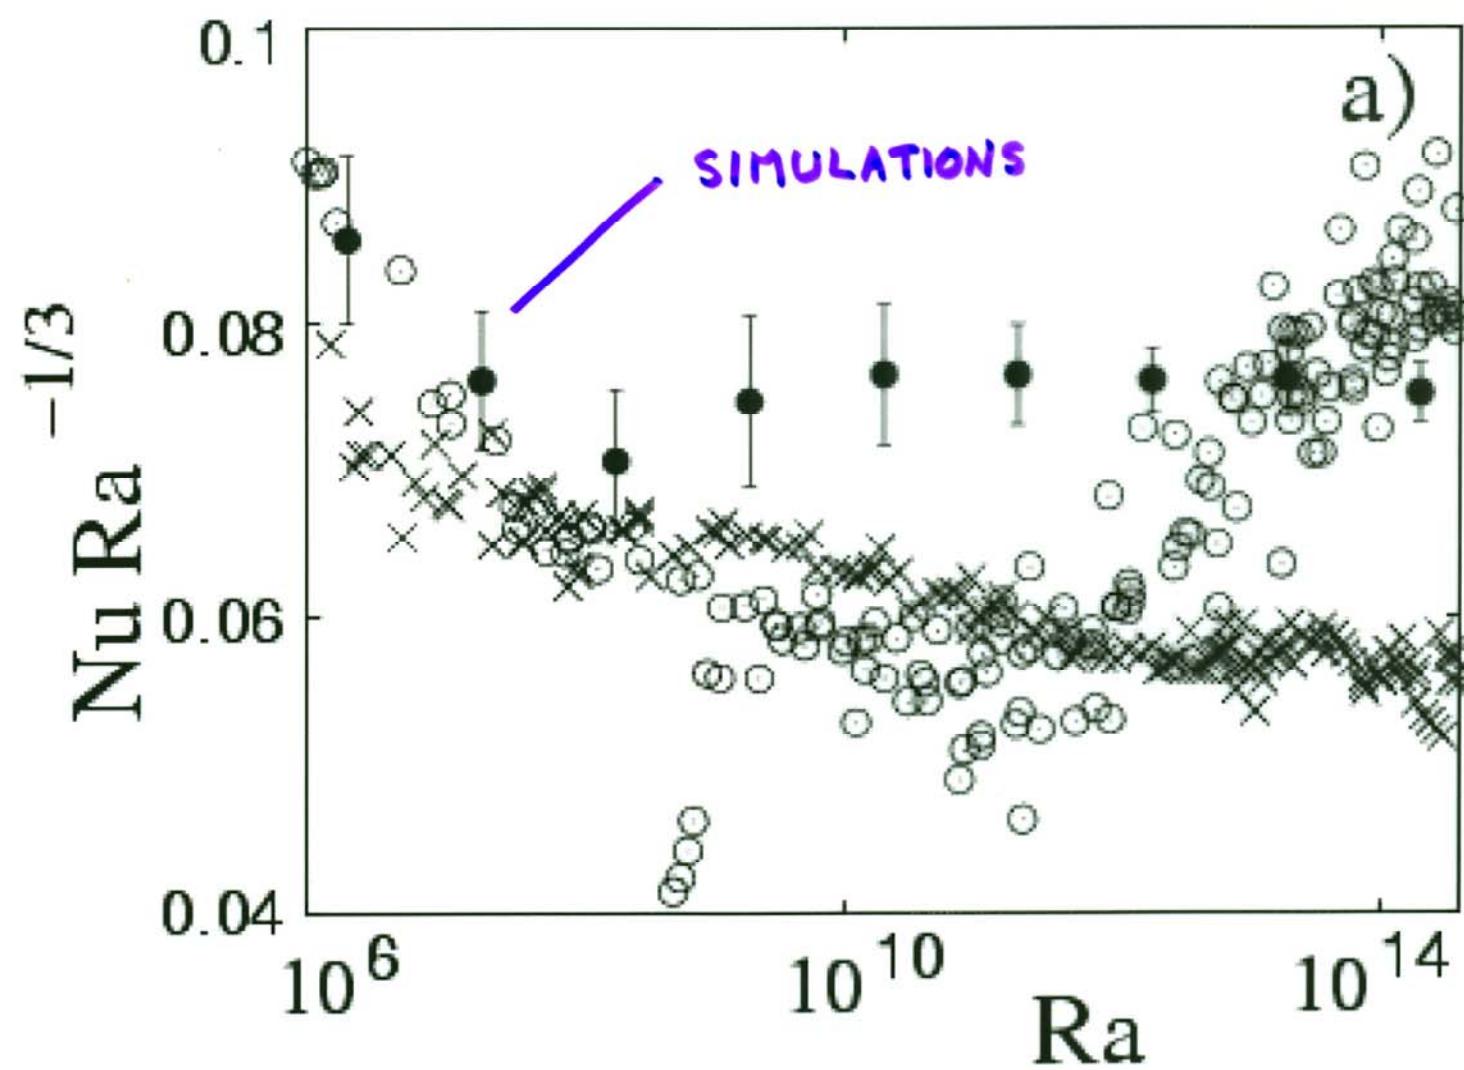

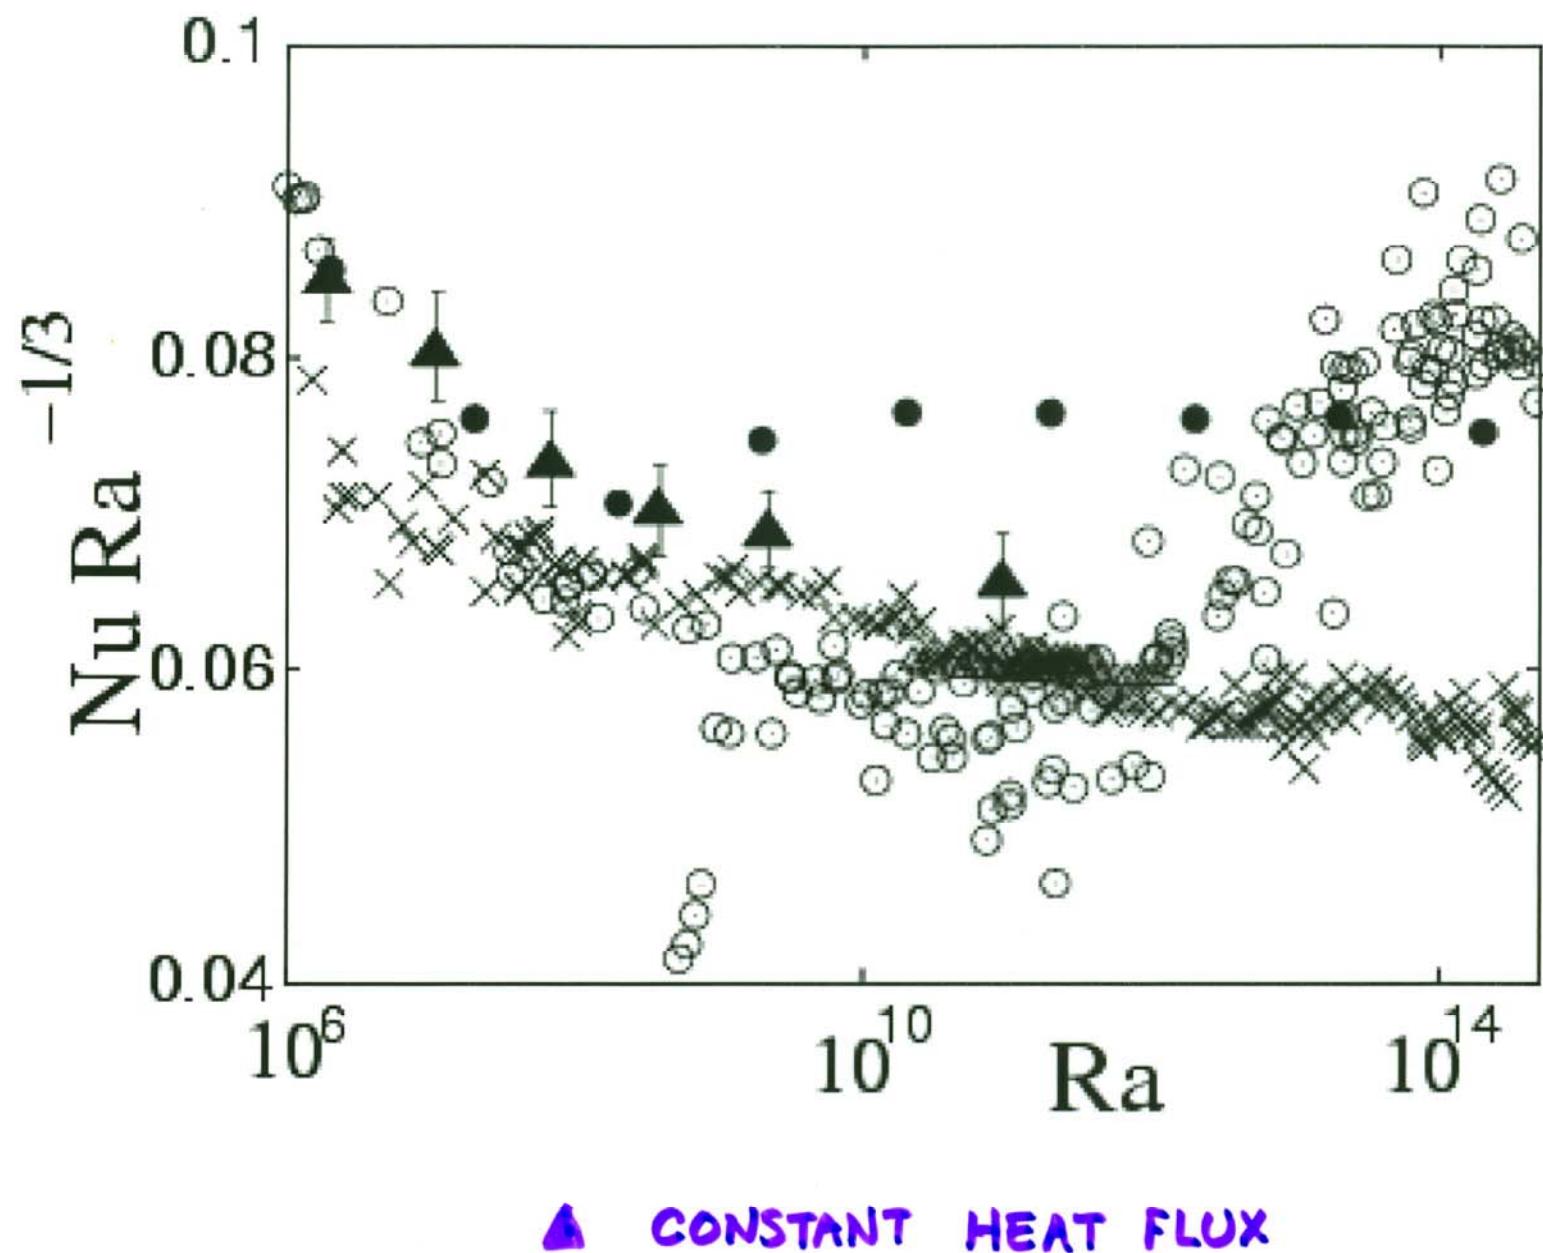

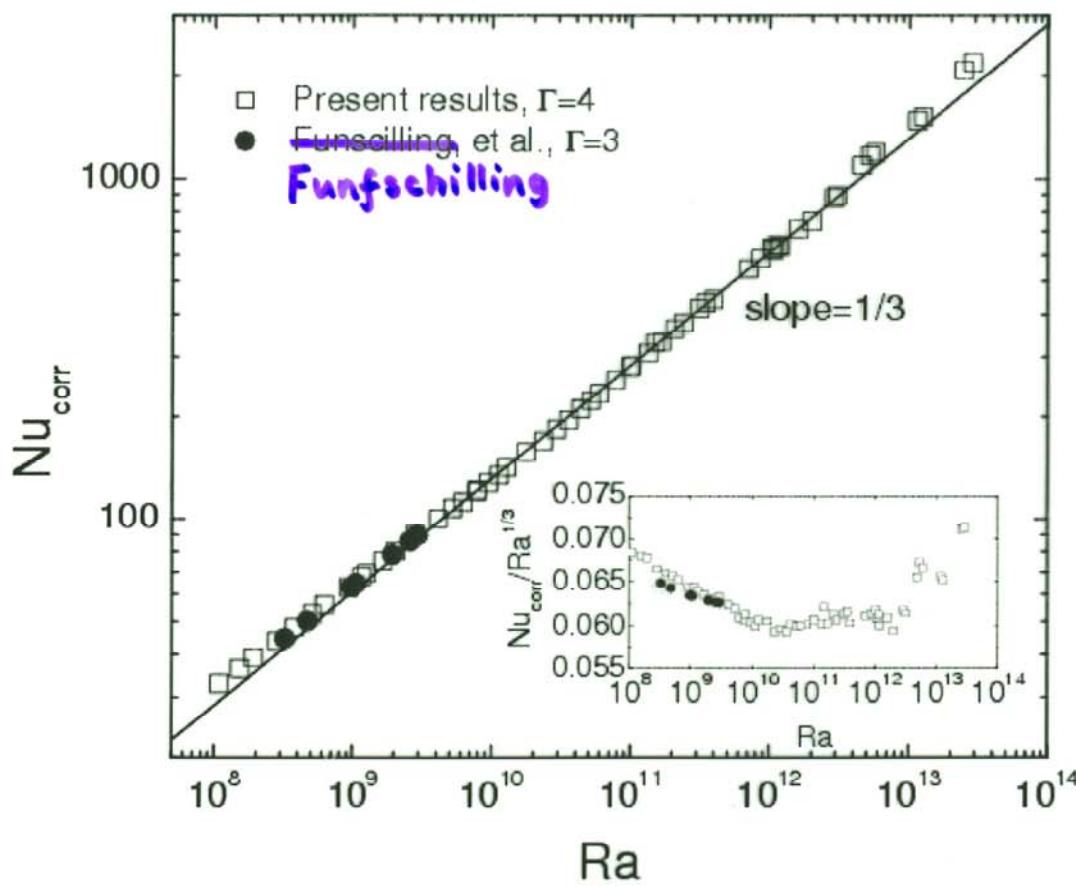

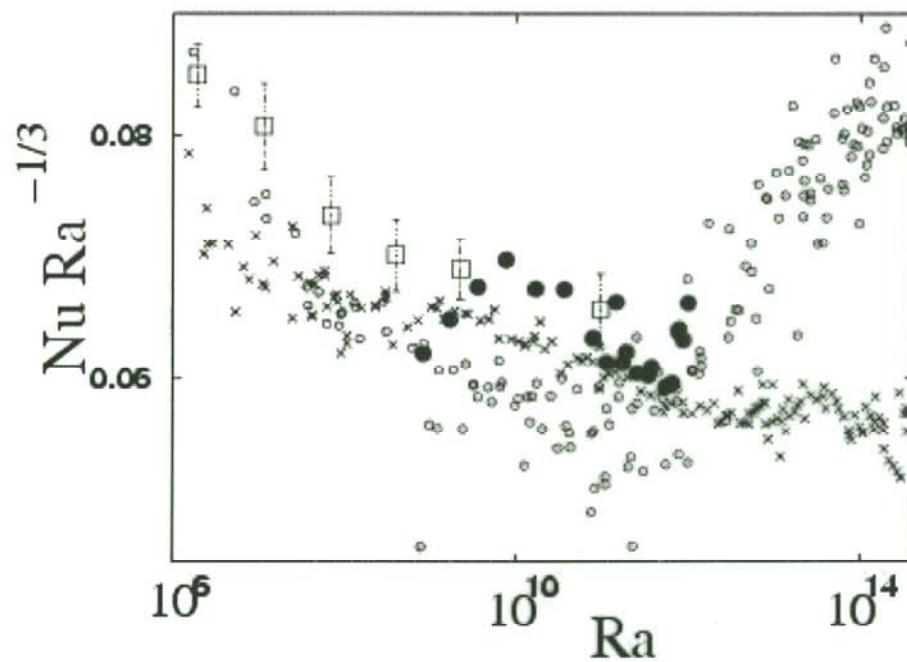

Niemela et al. (2000)

Niemela & Sreenivasan  
J. Fluid Mech 557, 411 (2006)

• du Puits et al. (2006)  
to appear

From these studies, it appears reasonable to state that the  $1/3$  is most likely power for Boussinesq convection for Prandtl numbers =  $O(1)$  and  $\Gamma = O(1)$ .

- What about Pr effects?
- What about  $\Gamma$  effects?
- What about  $Ra > 10^{14}$ ?
- What about n-B effects?

- More experiments are under way
- For now, I will use results from simulations

$$\begin{array}{l} \boxed{\text{Ra} = 10^{12}} \\ \Gamma = 1 \end{array}$$

slender

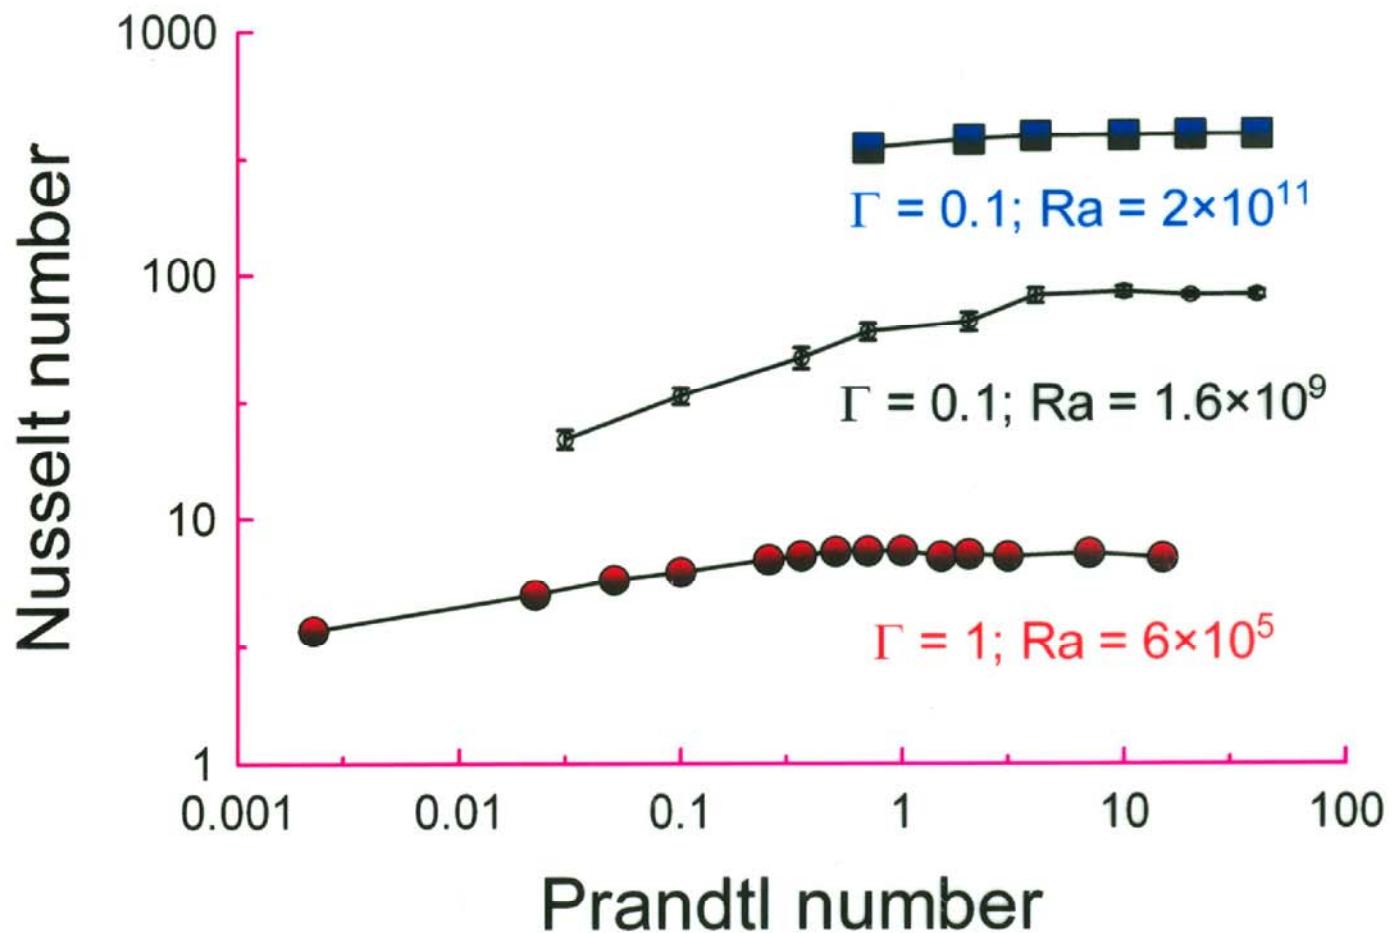

$$\boxed{\Gamma = 0.1}$$

Cigar

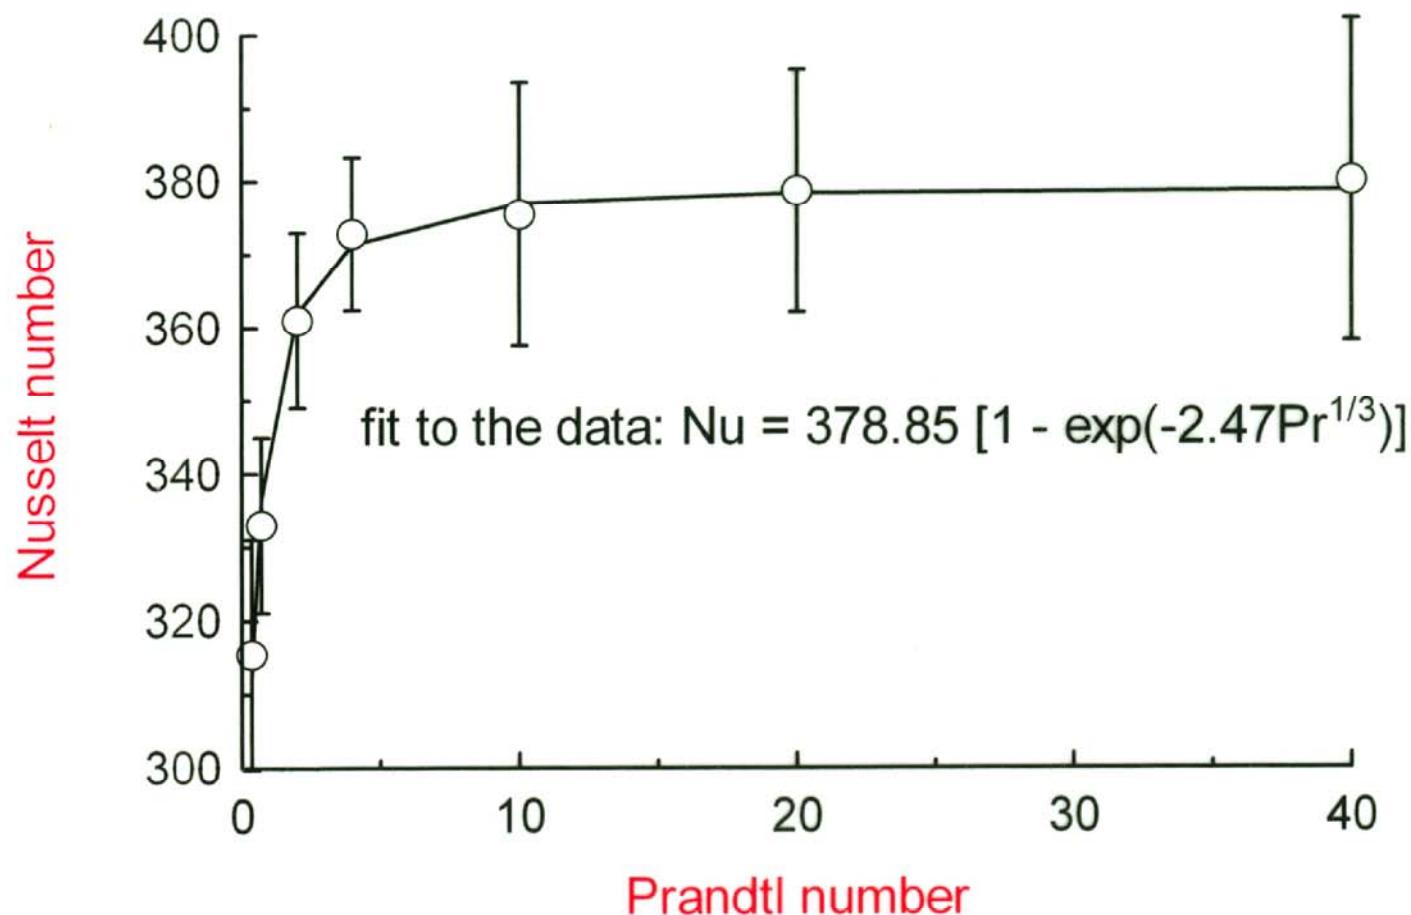

$$\text{Ra}_{0.1} = \text{Ra}_1 \Gamma^2$$

$\sim 10^{14}$  or so

## Prandtl number effects on heat transport

Nusselt number variation with Prandtl number  
Rayleigh number =  $2 \times 10^{11}$ , aspect ratio = 0.1

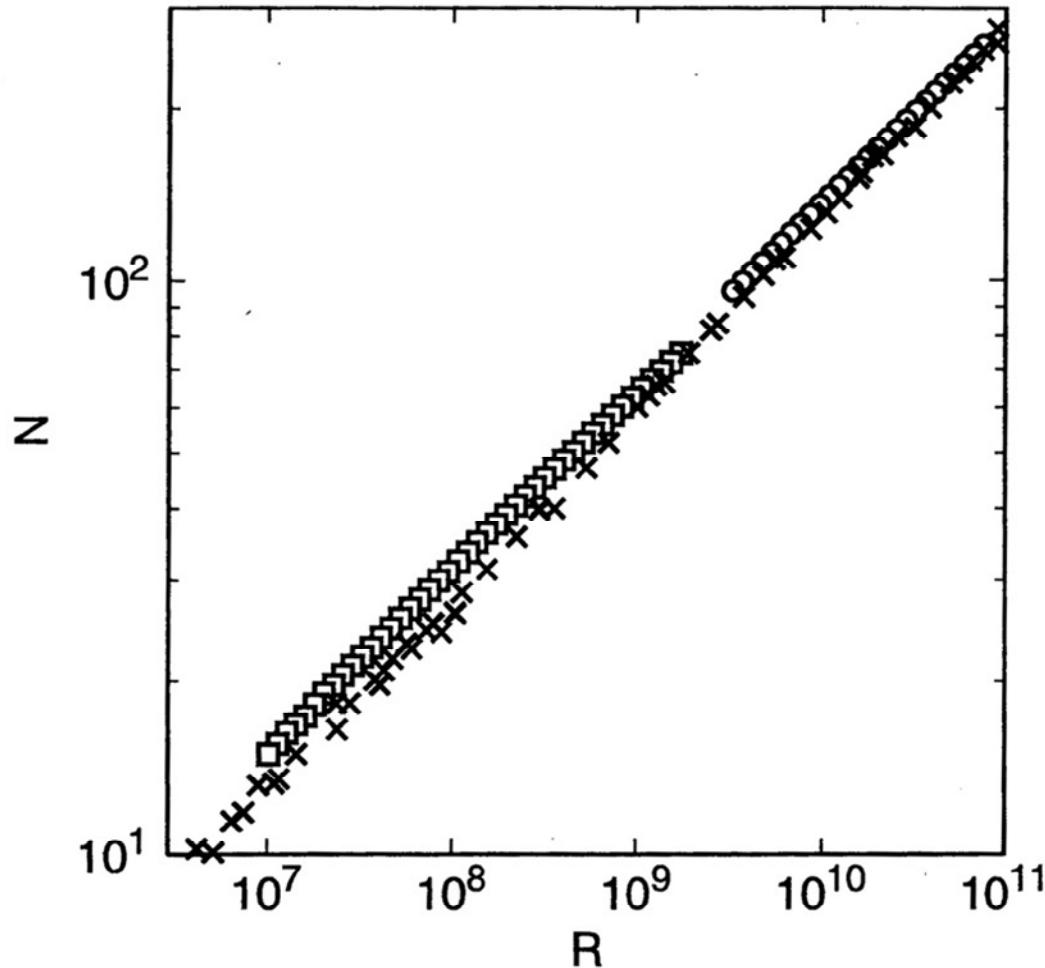

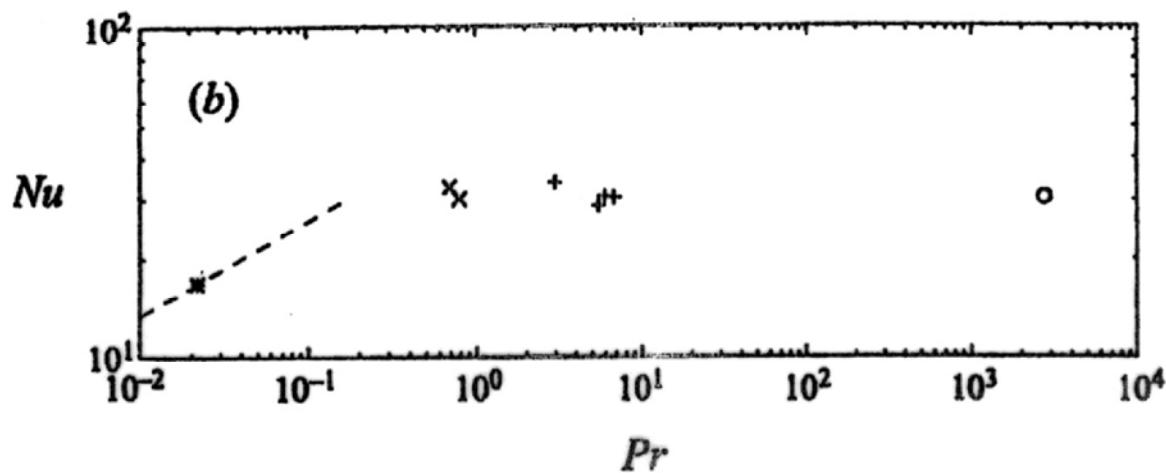

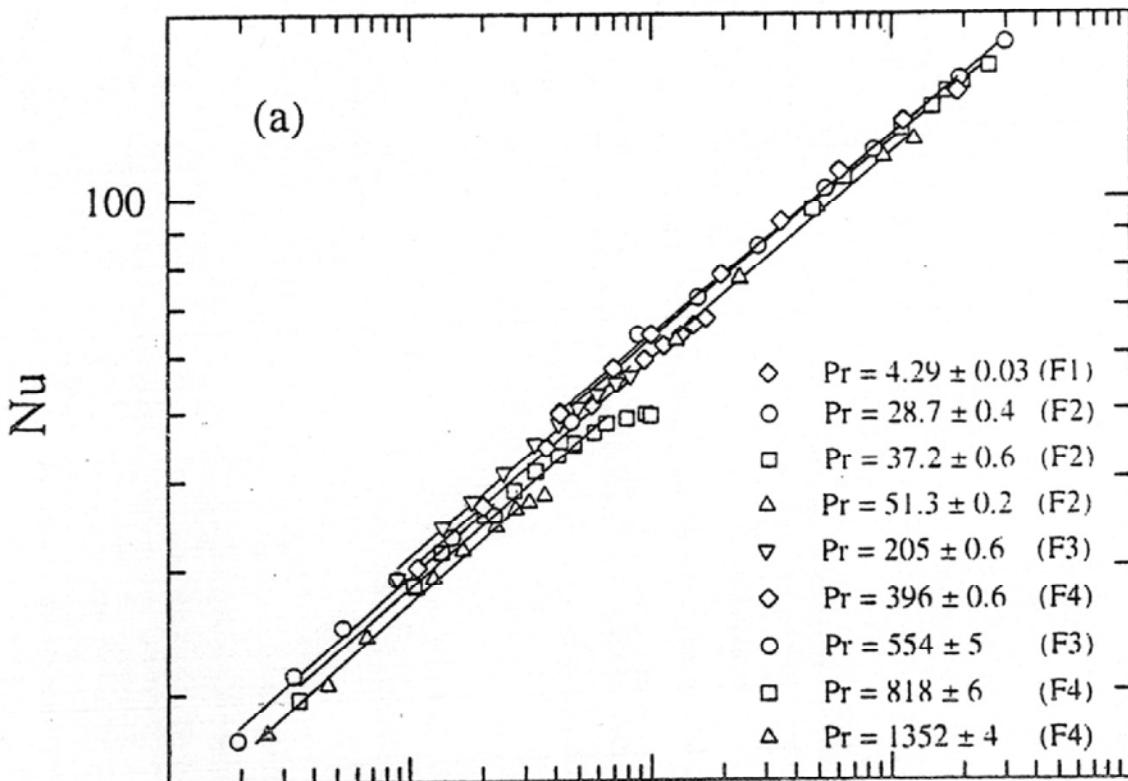

FIG. 2. The Nusselt number as a function of  $R$  on logarithmic scales for acetone ( $\sigma = 3.94$ ) and  $\Gamma = 0.5$  (open circles), and for 2-propanol ( $\sigma = 34.1$ ) and  $\Gamma = 1.0$  (open squares). The crosses are the data of Ref. [3]. A correction for the wall conduction based on model 2 of Ref. [6] was applied to all data.

G. Ahlers & X. Xu  
(Phys. Rev. Lett. 86, 3320, 2001)

Results collected by S. Cioni, S. Ciliberto & J. Sommeria (J. Fluid Mech. **335**, 111-140, 1997), from experiments on thermal convection in mercury, air, helium and water, and electro-chemical convection.  $\text{Ra} = 10^8$ . The dashed line to the left corresponds to  $\text{Pr}^{2/7}$ .

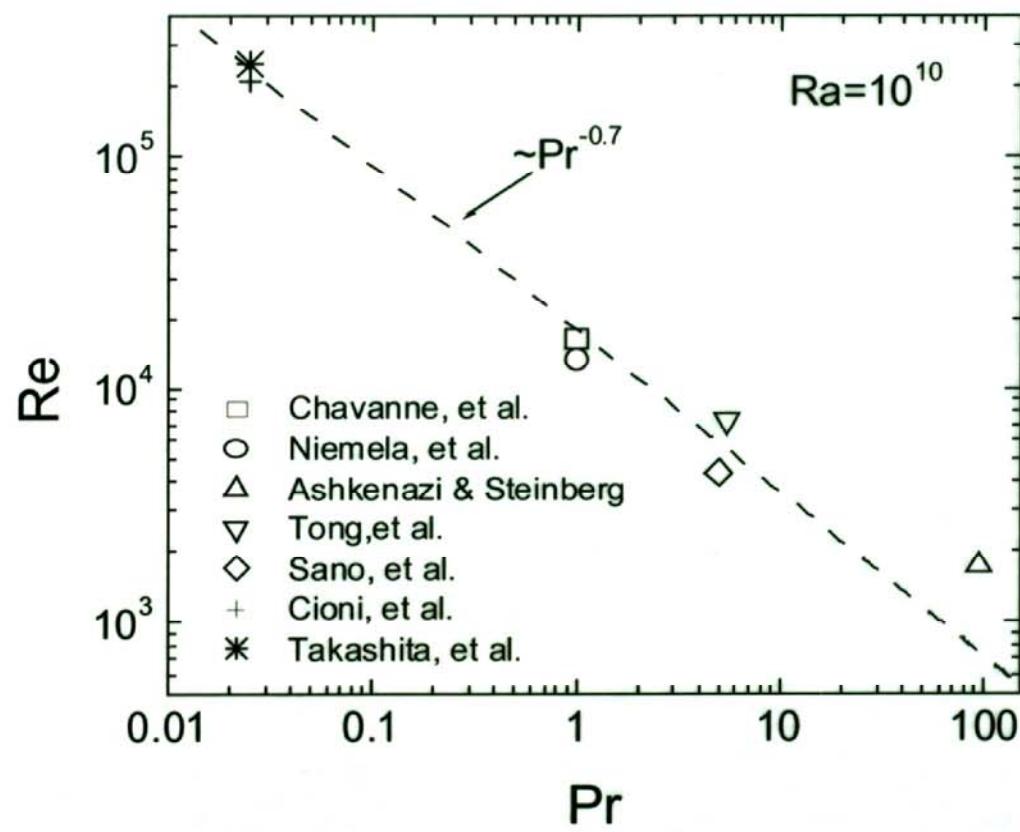

Data from K-Q. Xia, S. Lam & S-Q. Zhou  
 (Phys. Rev. Lett. **88**, 064501, 2002)

and all subsequent analyses. For the high- $\text{Pr}$  fluids, we find that after taking into account all the heat leakage the exponent  $\beta$  in general is increased by 0.04 as compared to that for the uncorrected data. Of this, roughly 0.025 to 0.02 can be attributed to corrections for leakage through the bottom plate, with the rest due to sidewall conduction. For water, the overall correction to  $\beta$  is less than 0.01. Note

## By the way

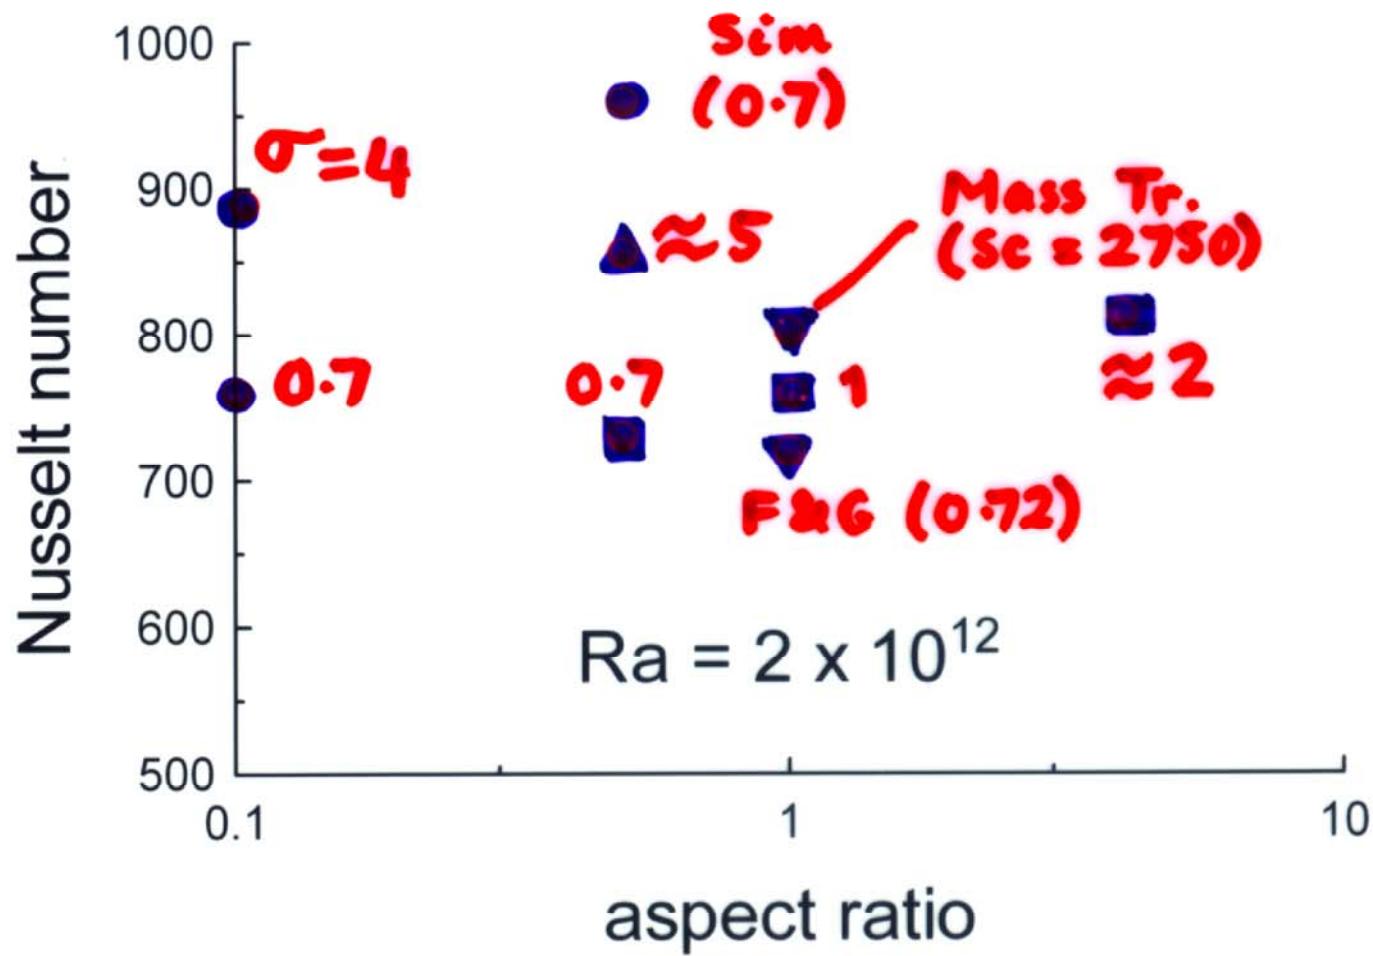

The formula found in the literature on free convection at high Rayleigh numbers

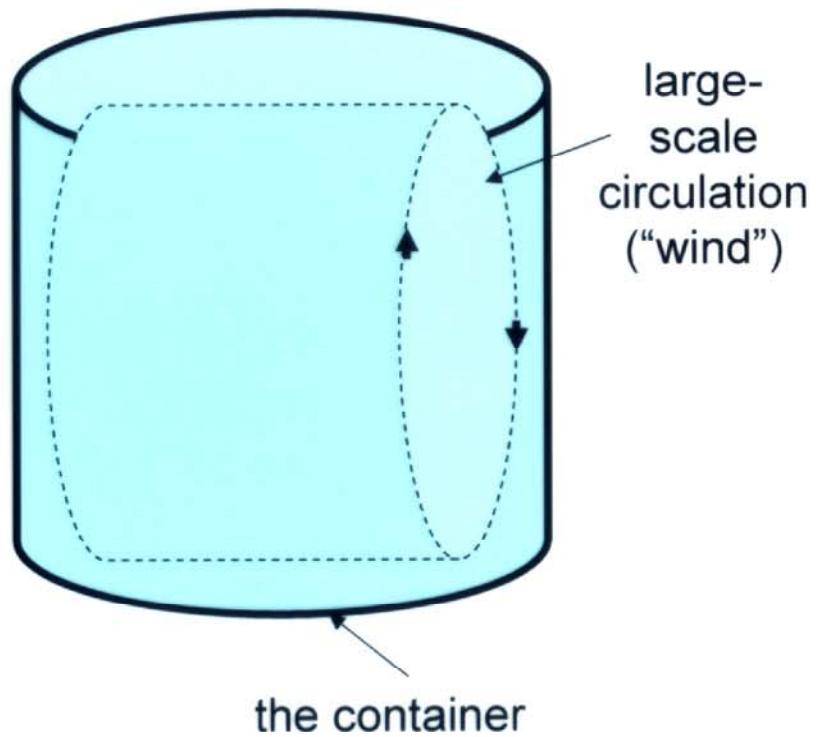

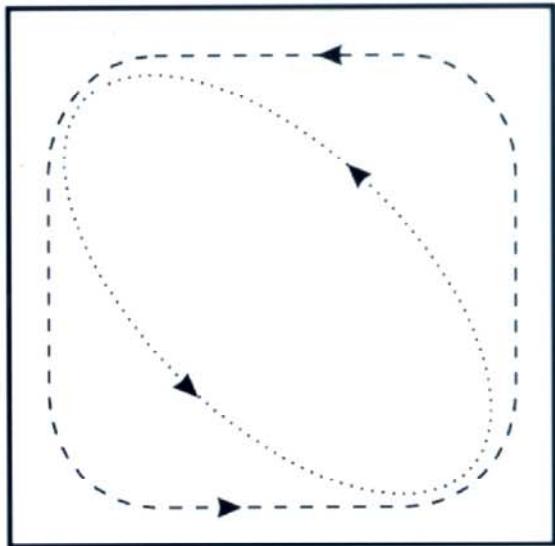

$$Nu = 0.067 Ra^{1/3} Pr^{-0.04}$$

$$\text{Re} = 0.2 \text{ Ra}^{0.49} \text{ Pr}^{-0.7}$$

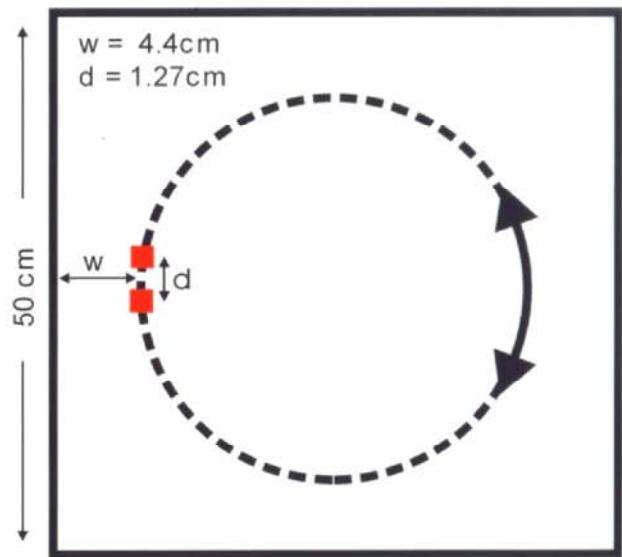

## aspect ratio effects

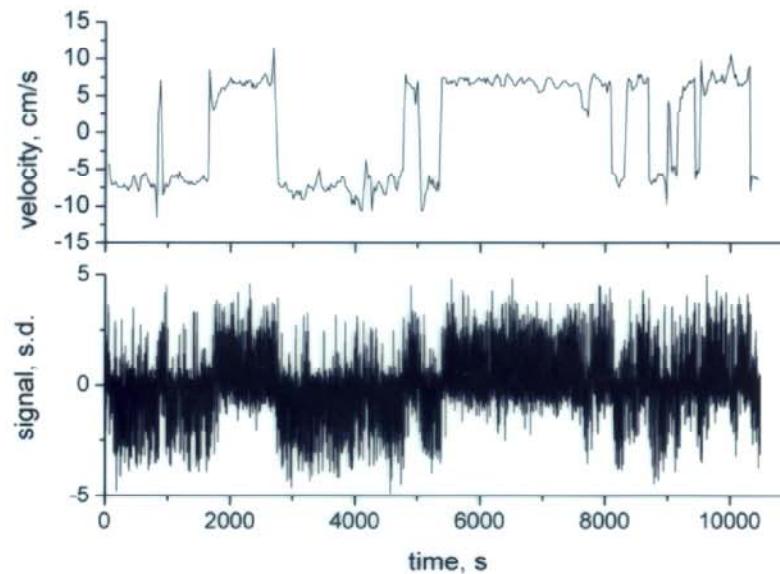

**The wind breaks the symmetry, with important consequences**

# The reversal of the mean wind

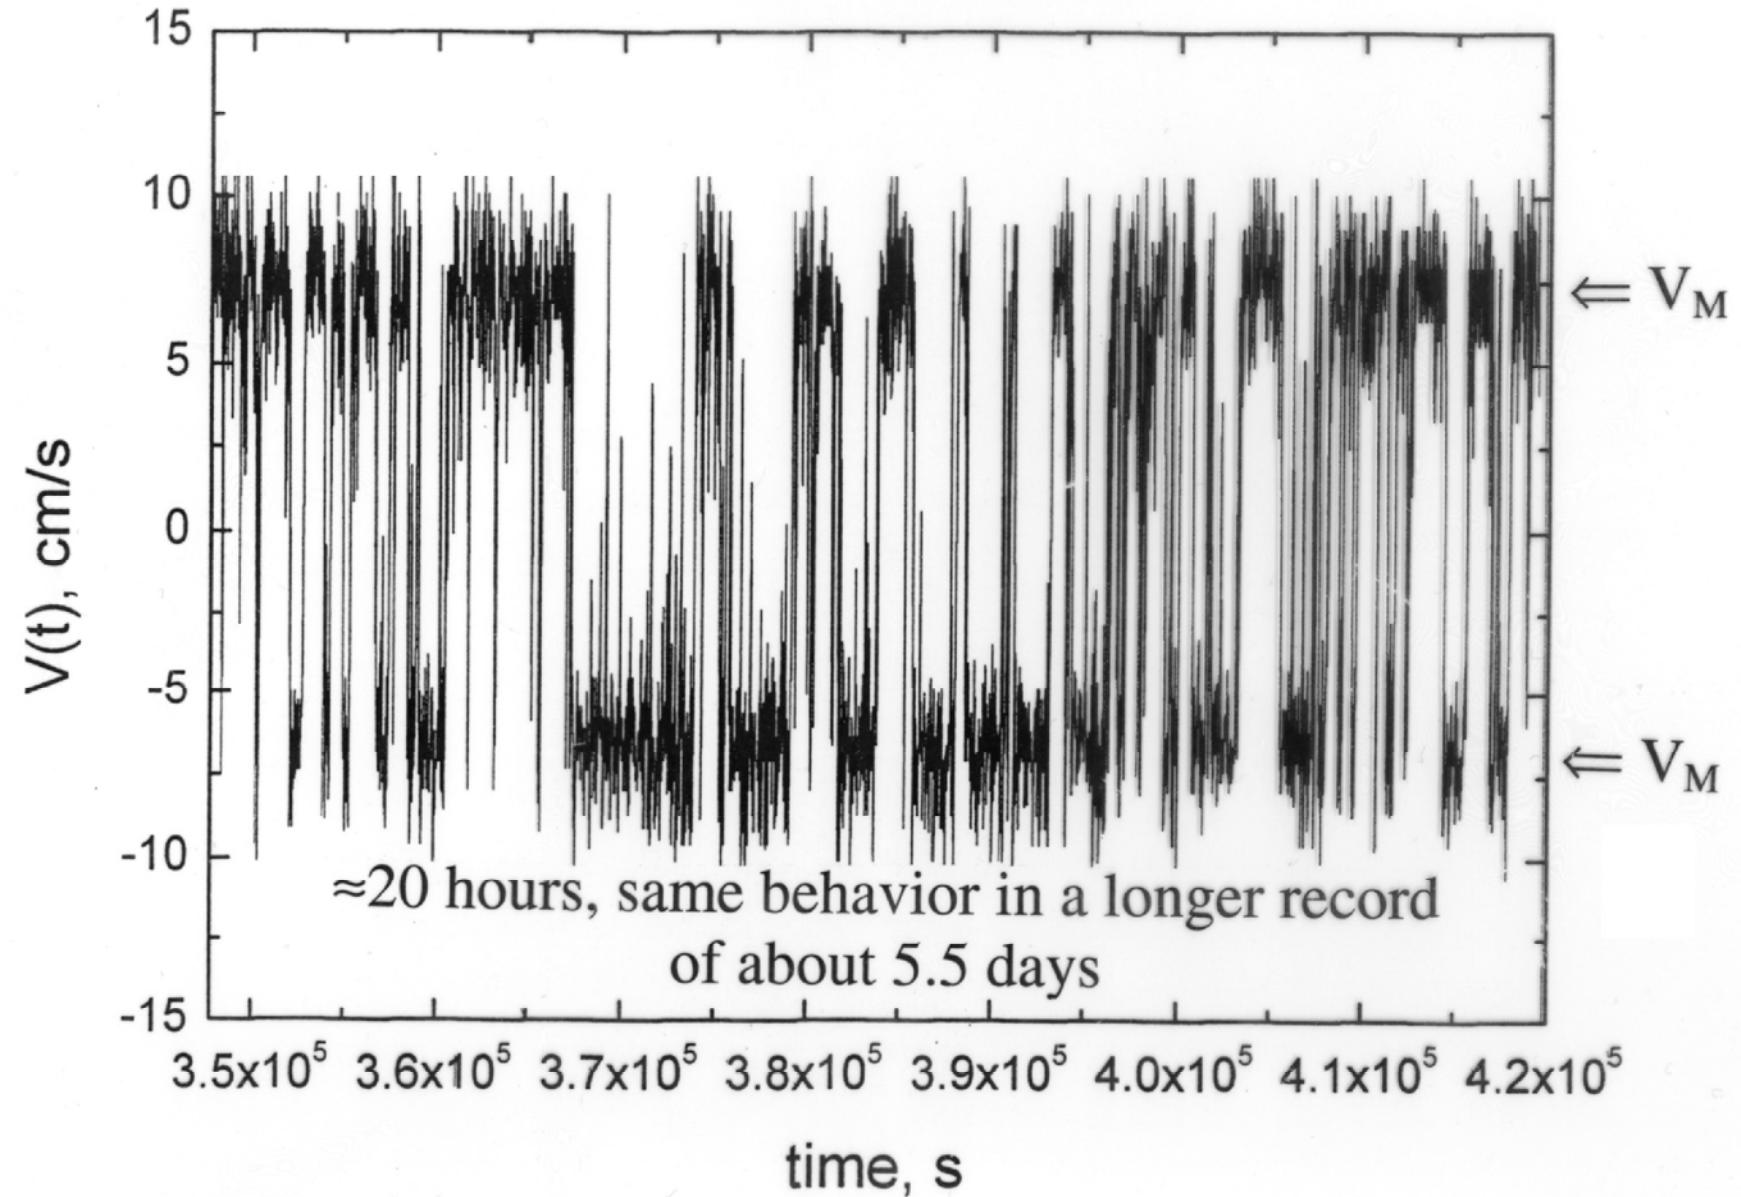

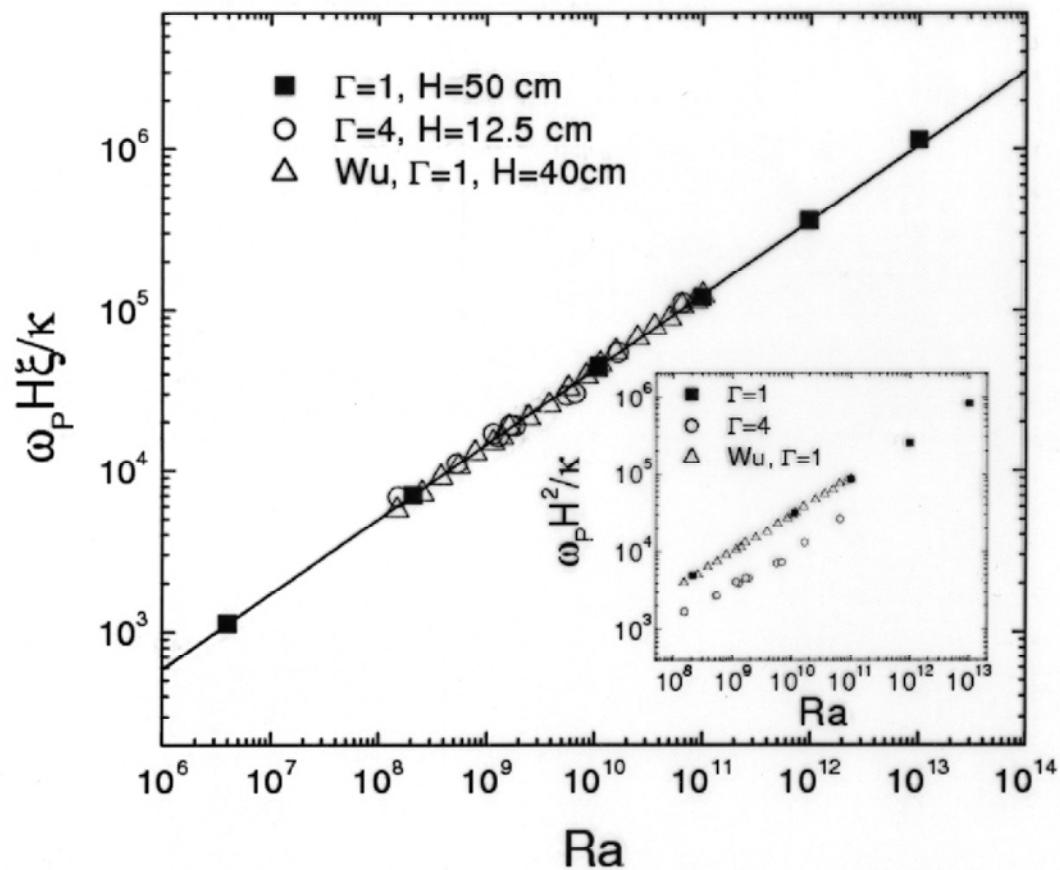

250-micrometer NTD-doped Ge sensors are placed in various positions in the flow.

Maximizing the correlation between temperature signals gives the magnitude and direction of a large scale circulation.

$$Ra = 1.5 \times 10^{11}, Pr = 0.7, \Gamma = 1$$

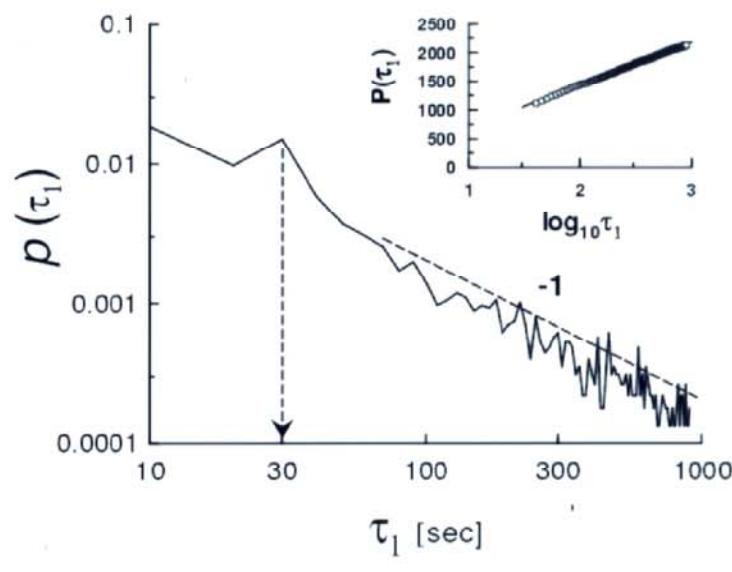

## How are the reversals distributed?

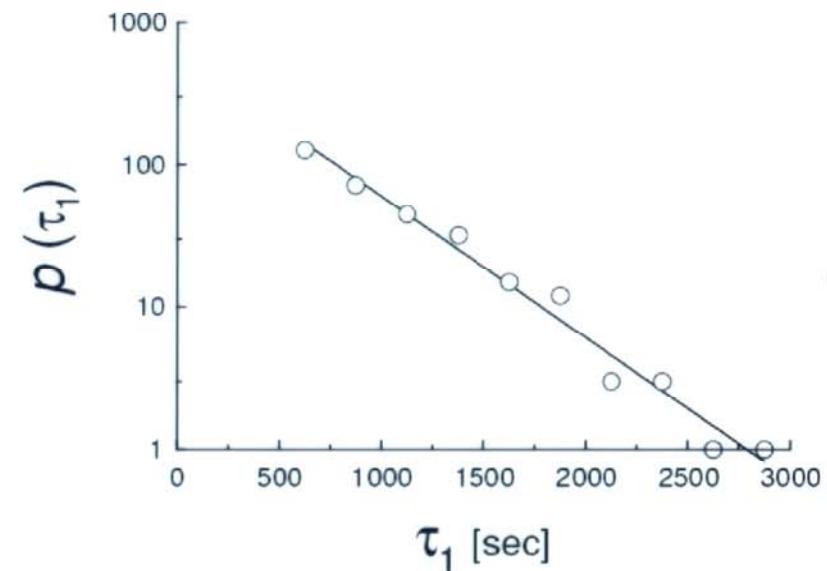

$\tau_1$  = time between subsequent switches in the velocity signal

$$\tau_1 \equiv T_{n+1} - T_n$$

Power-law scaling of the probability density function

For large  $\tau_1$ :  $p(\tau_1) \propto \exp[-(\tau_1 / \tau_m)]$   
 $\tau_m = 400$  s

Sreenivasan, Bershadskii & Niemela, Phys. Rev. E 65, 056306 (2002)

-1 power law scaling characteristic of SOC systems

## Summary remarks

- Fritz Busse is one of the greatest convection experts.
- Best research avenues to expand into are:
  - High-Ra--Pr = O(1)
  - High-Ra--low Pr
  - Moderate Ra--high Pr
- 1/3 power most likely correct
- Pr-effects are probably weak at high Ra
- Aspect ratio effects not too large
- We don't understand how to model non-B effects well.
- Reversals are qualitatively different from modest changes in direction or orientation. Full change of orientation appears quite unlikely.
- We have begun to understand how to model the dynamics of the mean wind.
