FOREWORD

Between April 2009 and February 2010 3 significant earthquakes occurred.

The study of these earthquakes provided a great increase of knowledge on causes and effects.

Herein some remarks on aspects concerning seismology and damage are presented and discussed. These two features are strongly correlated and therefore they must be studied together.

L'Aquila earthquake (Italy). April, 6 2009 Mw = 6.3

> Haiti earthquake. January, 12 2010 Mw = 7.0

> Maule earthquake (Chile). February, 27 2010 Mw = 8.8

Within the same period of time others earthquakes occurred, among which:

Baja California (Mexico). April, 4 2010 Mw = 7.2

Southern Qinghai (China). April, 13 2010 Mw = 6.9

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

The combination of seismology and seismic engineering is necessary to get robust assessment of scenario earthquakes.

➢ Without seismological information the interpretation of the buildings' behaviour during an earthquake is more difficult and sometimes more uncertain.

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

FIGURE 10.2 Basic steps of probabilistic seismic hazard analysis (after TERA Corporation 1978).

PSHA Probabilistic and DSHA Deterministic

procedures after Reiter (1990)

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Deterministic, or scenario, seismic hazard assessment can estimate several scenario earthquakes, even the largest possible, based on geophysical, geological, and geotechnical data and using appropriate numerical simulations of the rupture process and of wave propagation. This way it is even possible to assess reasonable ground motion signals.

In order to appraise earthquake damages both a robust seismic hazard assessment and a realistic buildings' vulnerability estimation are necessary.

PROBABILISTICS vs. OBSERVED VALUES

Kobe (17.1.1995), Gujarat (26.1.2001), Boumerdes (21.5.2003) Bam (26.12.2003), E-Sichuan (12.5.2008) and Haiti (12.1.2010) earthquakes PGA(g)

		Expected	Observed	Global Seismic	
		with a probability of exceedence of 10% in 50 years (return period 475 years)		Hazard Assessment	
•	Kobe	0.40-0.48	0.7-0.8	Program (GSHAP)	
•	Gujarat	0.16-0.24	0.5-0.6	Why are	
•	Boumerdes	0.08-0.16	0.3-0.4*	observed values	
•	Bam	0.16-0.24	0.7-0.8	expected ones??	
•	E-Sichuan	0.16-0.24	0.6->0.8		
•	Haiti	0.08-0.16	0.3-0.6*		

3

Past probabilistic hazard assessments have not always been confirmed by strong ground motion recordings and by damage observations.

Probabilistic hazard assessment improves with higher quality historical data. Nonetheless, often historical data is available for too short time windows. Moreover, several uncertainties are still present in the available models. i.e. Attenuation relations assume the same propagation model for all the events, but such hypothesis is not very realistic.

> Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Trieste, May 13, 2010

ATTENUATION

Empirical relations are not capable to capture relevant aspects of the phenomenon of space attenuation of peak values.

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Trieste, May 13, 2010

Pagina 8

Δ

Stability tests increased in the last 500 years with respect to that of the period 1000-1500.

This suggests that the available data from past events may well not be representative of future earthquakes and that the use of independent indicators of the seismogenic potential of a given area is needed.

ACCELERATION PARAMETERS: - PGA (PSHA) - EPA - DGA

PGA (used in PSHA) is the horizontal peak ground acceleration with 10% probability of exceedance in 50 years. This quantity is obtained treating probabilistically both the available data about the seismicity observed within each Seismogenic Zone and the propagation of seismic waves (attenuation relations).

NOTE: PGA is not an instrumental value, in fact it derives from probabilistic analyses.

EPA (Effective Peak Acceleration) is defined as the average of the maximum ordinates of elastic acceleration response spectra (5% damped) within the period range from 0.1 to 0.5 seconds, divided by a standard factor of 2.5.

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Trieste, May 13, 2010

L'Aquila EQ - Seismic demand Comparison EPA and instrumental PGA

Record -	PGA	PGV	EPA _(0.1-0.5)	S _{d,max}
main shock	(g)	(cm/s)	(g)	(cm)
AQV_EW	0.626	36.7	0.471	12.2
AQV_NS	0.598	40.5	0.502	8.0
AQG_EW	0.416	33.6	0.316	13.1
AQG_NS	0.434	35.9	0.309	12.0
AQA_EW	0.394	30.5	0.254	10.1
AQA_NS	0.451	24.5	0.384	7.2
AQK_EW	0.342	30.3	0.220	24.2
AQK_NS	0.340	38.6	0.245	22.6
AQU_EW	0.263	20.6	0.209	9.5
AQU_NS	0.316	30.7	0.157	12.4

• PGA and PGV are instrumental peak

• EPA gives a measure of the ground motion intensity in terms of acceleration and at the same time is related to the structural response. **The observed damage is consistent with EPA**

• S_{d,max} is the maximum spectral displacement.

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

DGA (DSHA) is the horizontal acceleration anchoring the elastic response spectrum at the period T=0 s, computed from the response spectrum obtained through the modelling of the ground motion caused by the strongest earthquakes observed in each cell falling in the Seismogenic Zones. Introduced by Prof. G. Panza.

DGA is practically equivalent to EPA.

The comparison between DGA and PGA (return period 475 years) is possible only in Italy thanks to the uniqueness of the length of its earthquake catalogue.

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Prof. Panza stated:

The comparison of the seismic hazard maps produced for Italy by the PSHA and NDSHA approaches shows that, as a rule, NDSHA provides values larger than those given by the PSHA in high-seismicity areas and in areas identified as prone to large earthquakes, but where no strong earthquake has been recorded in the last 1000 years.

L'Aquila earthquake April 6th, 2010

>On April 6, 2009 (1:32 UTC) an earthquake of magnitude M_w 6.3, originated by a normal fault rupture, shook the Abruzzo Region of Central Italy causing 309 death, hundreds of injured and thousand of homeless. It is the strongest earthquake recorded in Italy since 1980 (Irpinia earthquake).

L'Aquila city was located in near-fault position.

➤The focal mechanism exhibits the same direction as many of the major tectonic structures visible on the surface.

Affected population > 70 000 – 80 000
 Casualties ~ 309
 Homeless ~ 50 000 - 20 000 (depending on the date)
 Preliminary loss estimation ~ € 16-18 Bi

L'AQUILA EQ - RECORD AQK STATIONS

For records AQK and AQU (two station closer to downtown L'Aquila). Intense double sided velocity pulses are quite distint on both records.

This pulses occuring in the beginning of strong shaking are typical of near-fault motions and they impart significant input energy to structures.

The duration of strong shaking is short (between 3-10 seconds).

The extent of damage was limited by the short duration. The number of Yielding Reversals NYR is low.

SPECIFIC ASPECTS

Trieste, May 13, 2010

Plate tectonics. European region. Simplified scheme

Large earthquakes originate mainly on a narrow belt along the central Appennines, accommodating a NE-trending extension, with a rate of about 3mm/yr. The geological model of plate tectonics provides the most coherent global explanation of the occurrence of the majority of earthquakes.

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Trieste, May 13, 2010

L'Aquila earthquake - Seismology Focal mechanisms, seismic sequence

The main shock was preceded by a sequence of foreshocks, which started several months before, with a significant shock of magnitude M_w 4.4 on 30th March and culminating with a M_L 3.9 and a M_L 3.5 shock about 5 and 3 hours before the main event, respectively.

Subsequent to the main shock, many aftershocks were recorded, including seven aftershocks of moment magnitude larger than or equal to 5.0. Initially, the aftershock activity occurred near L'Aquila and towards S-SE of the town, whereas a couple of days later it migrated towards the north. In particular, a M_W 5.6 event occurred on April 7 at 17:48 UTC in the Aterno Valley, about 4 km SW from the village of Fossa, whereas on 9 April at 00:53 UTC an event of MW 5.4 took place near Campotosto about 16 km northwards L'Aquila

Directivity and Macroseismic intensity

➤ The main shock nucleated at a shallow depth of 9 km, with the hypocenter located close to the north-western border of the surface projection of the fault, with a possible directivity-induced amplification effects due to both up-dip and along-strike rupture propagation that could have contributed to the increase of the damage pattern in L'Aquila and in the villages located to the southeast.

L'Aquila city, which was severely damaged by the event, is located about 6 km from the epicentre in hanging wall position.
Macroseismic intensity, according to the MCS scale (Mercalli Cancani Sieberg) was X in the little village of Onna (located to about 10 km from L'Aquila) and IX in L'Aquila city.

The geographical position of the considered stations is shown in Figures. Two stations are located near downtown L'Aquila (AQK, AQU) and near to heavily damaged areas, three in the Aterno Valley (AQA, AQG, AQV) and two at NE of the Aterno Valley (AQF, AQP).

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Trieste, May 13, 2010

L'Aquila EQ – Displacement Demand

The analysis of the displacement demand is of fundamental importance both for the application of the displacement-based design and for the design of base isolated structures. Moreover, it is a good indicator of the earthquake damage potential.

On the whole, the displacement demand is moderate, indicating a non-extraordinary event. The displacement demand does not exceed 13 cm with the exception of AQK records, which show maximum values of 24 cm and 22 cm for the component EW and NS, respectively.

The displacement demand increases in the range of period from 0 to about 1-1.5 s and then remains constant or decreases. This trend is consistent with that gathered from the study of a large number of accelerograms.

Displacement spectra of the near-fault records compared to the spectra proposed for design (Decanini et al. 2003) for soil S1 (rock or stiff soil) and S2 (intermediate soil).

Strong ground motion records – main shock parameters

PGA and PGV are instrumental peak

A useful parameter, which can give an indication of both the spectral values and the spectral shapes, is the effective peak acceleration (EPA), which is given by the average pseudo-acceleration in the period range 0.1-0.5 s divided by 2.5. The EPA gives a measure of the ground motion intensity in terms of acceleration and at the same time is related to the structural response.

S_{d.max} is the maximum spectral displacement

IV is the maximum incremental velocity, given by the area enclosed by the largest acceleration pulse

I_A is the Arias intensity

 I_{H} is the Housner intensity

Luis Decanini

Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

L'Aquila earthquake - Force Demand

The reduction of the force demand due to the ductility is remarkable. In mean, the reduction of the peak values with increasing ductility is equal to 35%, 45% and 60% for ductility equal to 1.5, 2 and 4, respectively. The elastic acceleration spectrum is not always a good indicator of the destructiveness potential of a ground motion. In fact, the observed damage, especially in reinforced concrete buildings, seems not consistent with the high elastic strength demands depicted in the spectra.

L'Aquila EQ – Input Energy demand

Absolute elastic input energy spectra for unit mass are plotted in figures

The maximum demand in terms of energy occurs at periods greater than those related to the maximum values of the pseudo-accelerations.

The AQK spectral shapes differ noticeably from the others, in fact the peak values occur at about 1.7 s, the same period value was found for the maximum displacement demand. The AQK records could have been affected by local effect.

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Trieste, May 13, 2010

L'Aquila EQ – Input Energy Demand (elastic and inelastic)

The input energy constant ductility spectra show a shift of the peak values towards higher frequencies. The effect of ductility on the maximum spectral values is less marked than in the pseudo acceleration spectra.

> The energy demand related to the aftershocks is low, the comparison with the main shock highlights a remarkable decrease

L'Aquila EQ – Input Energy Demand

To measure the global demand in terms of energy, the parameters $AEI_{(0-2)}$ and $AEI_{(0-4)}$, given by the integral of the absolute elastic input energy per unit mass (5% damped) in the range of periods 0-2 s and 0-4 s (Decanini & Mollaioli 1998) were estimated. The energy demand varies significantly among the different accelerograms reaching the maximum values for AQK and AQV records. These energy parameters are not well correlated to the instrumental PGAs, better correlations are obtained with the PGVs and the maximum spectral displacements S_{dmax} .

For L'Aquila event, a general agreement between observed damage and displacement, energy and inelastic force demands has been observed.

It seems that displacement and energy demand together could give a good estimate of the earthquake damage potential.

Masonry and reinforced concrete buildings Courtesy of Giacomo Di Pasquale Office of Seismic Risk Reduction

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Trieste, May 13, 2010

Introduction

Most of the RC buildings existing in this area are designed with elderly seismic codes. Moreover, they may present deficiency both in the structural configuration and in detailing design and construction due to lacking of appropriate application of the code or to incorrect application of their rules.

Reinforced concrete buildings in L'Aquila, constructed in different eras probably starting from the thirties, possess very diverse characteristics in terms of both strength and ductility. From the last ISTAT (Istituto Nazionale di Statistica) building census, the RC buildings in L'Aquila amount to 4113, which is about the 29% of the total building stock.

Despite some noticeable cases of collapse, the majority of RC frame buildings in L'Aquila town centre were not structurally damaged but sustained extensive non-structural damage. It is worth mentioning the total amount of **RC buildings with total collapse is less than 1% of those existing in L'Aquila city showing high individual vulnerability**. This small percentage is maybe due to the short duration of the ground motion and to the presence of infills, which in many cases prevented the development of structural damage.

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Trieste, May 13, 2010

Structural layout

The observation of damages highlighted how structural irregularities, like:

- presence of moment resisting frames only in one direction of the building
- weak column/strong beam (bad hinges pattern)
- inadequate column cross sections
- abrupt change of vertical resisting systems in elevation
- abrupt change of strength and stiffness in elevation
- interruption of vertical loads resisting elements
- not compact configurations in plan
- large eccentricity in plan
- etc.

seriously compromised the stability of buildings.

In fact, these factors can cause important shaking variation that may include **soft storeys, short columns, significant torsion, pounding**, etc.

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Trieste, May 13, 2010

Infill masonry

The role of infills masonry was found to be substantial. In fact, the field survey showed the positive contribution of uniformly distributed infills and the high vulnerability of buildings when discontinuities of infills in elevation are present (open storey configurations).

The damage type most commonly observed in L'Aquila and the surrounding towns to RC frames was non-structural damage to exterior infill walls and interior partitions, varying from small cracks to collapse. Several buildings displayed complete loss of the masonry infill walls at lower storeys. There were also occurrences of out-of-plane failure of a single layer of the infills. Anyway, in many cases the energy dissipation in the infills walls allowed structures to survive the earthquake with minor or even without structural damage.

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Trieste, May 13, 2010

Structural deficiency

Structural deficiency can be caused by design or **construction** process and/or age. They include:

- inadequate stirrup in columns and transverse reinforcement not adequately anchored around the longitudinal bars or shear reinforcements (stirrups) absent or having large spacing
- lack of stirrups in columns and beam-column joints, deficient detailing
- lack of adequate anchorage in smooth reinforcement
- eccentric beam-column joint
- poor quality of concrete
- lack of adequate anchorage length
- inadequate upper rebars in beam
- inadequate lap splices

Concerning the **quality of concrete**, in general it varies from **bad to medium**, with a **great variability** from one point of a building to another point, perhaps due to the fact that the concrete was usually made in situ. Local defects in concrete were also observed, like segregation, cold joints, etc.

Trieste, May 13, 2010

Introduction

Damage to historical masonry buildings has been more widespread than that to reinforced concrete buildings.

Often the masonry quality is poor.

The churches have been more affected compared to residential buildings, also due to the higher horizontal and vertical walls slenderness.

The pattern of damage in the churches is similar to that of previous Italian earthquakes.

Historical centre have suffered the interruption of several streets due to out-ofplane collapses of façades. This has hampered the evacuation, happened at night perhaps without electrical lighting, and the following relieves.

Past interventions, especially those using reinforced concrete elements, have sometimes caused more damages, compared to similar edifices with traditional details.

Damages of Chile EQ - Masonry buildings

Masonry buildings (Astroza 2010)

Adobe (unfired bricks) buildings have shown a very poor performance, characterised by extensive collapses. This is the case especially in Regions VI and VII (O'Higgings and Maule). Chilean investigators professor Maximiliano Astroza and Mister Francisco Cabezas, Universidad de Chile, use the term *adobicide*.

A large number of such buildings are currently unsafe to use, pending a demolition order. Therefore, the demand for residential units has markedly increased. This phenomenon has been worsened by the coming on of the winter.

Chilean academics are inclined to forbid adobe constructions.

Damages of Chile EQ - Masonry buildings

Masonry buildings (Astroza 2010)

- The behaviour of **confined masonry** buildings has been usually **very satisfactory**, even when they have been built directly by the owners.
- The percentage of severely damaged masonry edifices has been low. Moreover, such damages has been observed mainly in buildings that have been tampered with (removed walls, cut vertical and/or horizontal RC beams) or where site effects have been very marked (building on or at the top of steep slopes).
- These observations confirm what already highlighted by all severe earthquakes since the Chillan 1939 event.
- Therefore the use of confined masonry shall be encouraged for buildings up to 4 stories.

Confined masonry

In *confined masonry* RC members are adherent to masonry walls, which are vertical load bearing.

This structural type is not considered in Italian Codes, while it is included in EC8 regulation.

The seismic behaviour of confined masonry buildings during several destructive earthquakes has been very satisfactory (Decanini e D'Amore 1993, Decanini 2005).

In Chile confined masonry buildings of one ore two storey are usual, their behaviour during 2010 earthquake was very good.

Damages of Chile EQ - Churches

• The performance of masonry churches has been usually poorer than that of residential buildings, due to higher vertical and horizontal slenderness.

- This is true especially for those edifices built by European architects in the second half of 19th century.
- However, their response need a specific study.

Santiago, Huérfanos esquina S.O de Almirante Barroso

Neogotic church (1870 - 1872). Severely damaged (partial collapses and shoring) during 1985 EQ. Only a chapel was used up to 1990. Thereafter closed. Dimensions: 98 x 37 m, internal height 30 m (capable of 5000 persons).

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Trieste, May 13, 2010

Santiago, Huérfanos esquina S.O de Almirante Barroso

> Brick masonry. Partial collapse of the left and right walls in the first bay; collapse of the left wall in the third bay; collapse of the second right pillar; third and fourth pillars reinforced concrete after the 1985 EQ; collapse of a large part of the timber false vault.

Basílica de Los Sacramentinos

Santiago, Santa Isabel con Arturo Prat

Design drawing dating 1923, by architect Ricardo Larrain Bravo. He spent several months in France after his graduation. The church is inspired to Sacre-Coeur, Paris. The 1923 design was much higher.

Trieste, May 13, 2010

Basílica de Los Sacramentinos Santiago, Santa Isabel con Arturo Prat

The church is completely built of reinforced concrete. It was one among the first in Chile. In the same era in Santiago other churches have been built using different techniques. Cold joints and gravel pockets are clearly visible.

Luis Decanini Some remarks on the earthquakes in L'Aquila, Haiti and Chile. Seismology and damages

Trieste, May 13, 2010

Basílica de Los Sacramentinos

Santiago, Santa Isabel con Arturo Prat

Damages to drum windows and overturning of the crosses on top of the façade lateral pinnacles (the south one due to the March 11th. aftershock). Torsion of the bell gable of the right pinnacle. Very limited cracks inside in the first bay of the central nave. In 1985 damages to façade crosses and dome.
