Abstract We present an atmosphere–ocean regional climate model for the Mediterranean basin, called the PROTHEUS system, composed by the regional climate model RegCM3 as the atmospheric component and by a regional configuration of the MITgcm model as the oceanic component. The model is applied to an area encompassing the Mediterranean Sea and compared to a stand-alone version of its atmospheric component. An assessment of the model performances is done by using available observational datasets. Despite a persistent bias, the PROTHEUS system

under strong air–sea interaction conditions. As a consequence of the model’s skill in reproducing observed SST and wind fields, we expect a reliable estimation of air–sea fluxes. The model skill in reproducing climatological land surface fields is in line with that of state of the art regional climate models.

Keywords Regional climate model · Mediterranean · Air–sea interaction

Small changes in land-use...

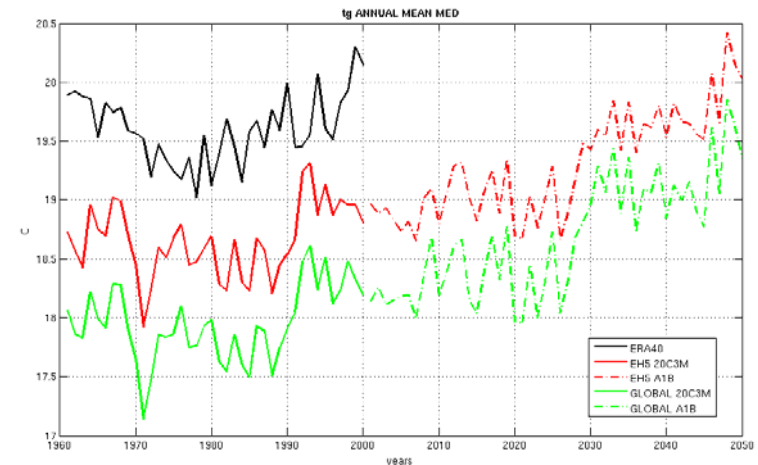

Present Climate Simulation : Major results

- 40-year simulation driven by ERA40 reanalysis at BC (just begun to analyse ERA-Interim)
- Realistic features reproduced (atmospheric circulations, land surface climate, ocean SST, ocean surface circulations and air-sea fluxes)
- Sea level anomalies correctly reproduced
- The coupling does not affect the bulk characteristics of the atmospheric model
- The coupled model is capable of significantly improve the description of air-sea interactions in terms of sensible and latent heat, especially at small scales and for intense events
- Locally, the coupling could affect the rainfall statistics

PROTHEUS SCENARIO Simulation: preliminary analysis

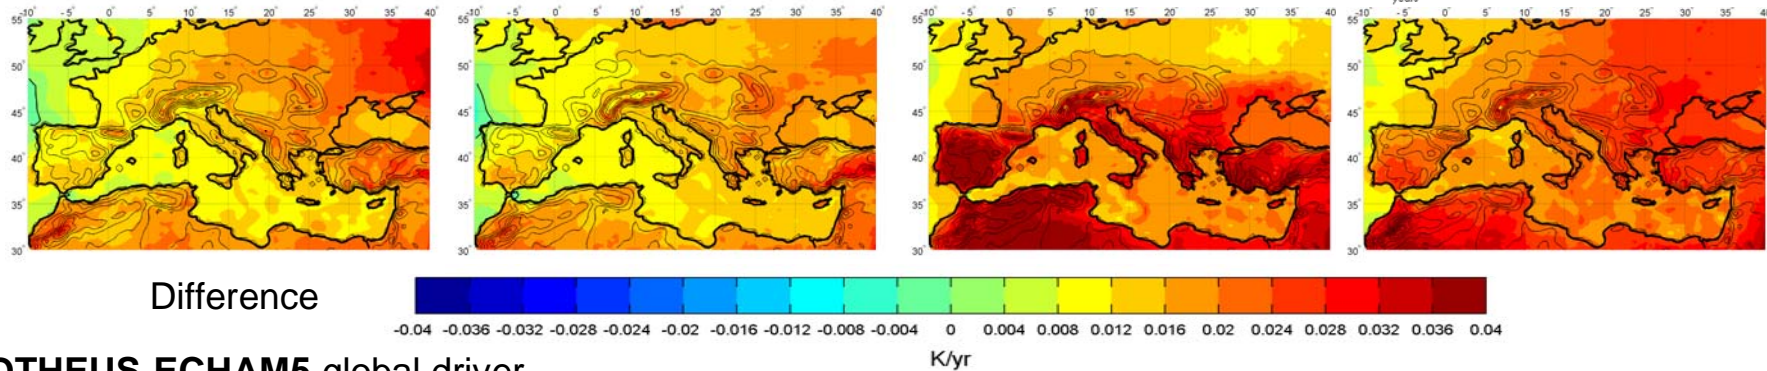

- Planned simulations in the framework of **Med-Cordex** (ERA-Interim, METEO-FRANCE, ECHAM5-MPIOM, CMCC...)

Preliminary analysis first SCENARIO
Simulation: Major results

- Simulation: 1951-2050 ECHAM5-MPIOM at BC (20c3m for 1951-2000 and SRESA1B for 2001-2050)
- Upward trend in Surface Temperature detected in PROTHEUS Scenario simulation
- Trends in PROTHEUS significantly lesser than the corresponding ones in the global simulation, especially over the sea and over mountain regions
- Strong seasonality in PROTHEUS E-P surface flux trend and, consequently, in river discharges
- Sea level changes detected (steric sea level rise)
