Nonlinear Schrödinger equation

$$i\psi_t + \nabla^2\psi \pm |\psi|^2\psi = 0$$

describes the evolution of a temporal envelope of a spectrally narrow wave packet, independent of the origin of the waves and the nature of the nonlinearity

Benney & Newell (1967) — general settings

Zakharov (1968) — deep water waves

Hasegawa & Tappert (1973) — optical fibers

Why universal?

Linear wave:

$$\frac{\partial a}{\partial t} + v \frac{\partial a}{\partial x} = 0$$

$$\frac{\partial a_k}{\partial t} + i\omega a_k = 0$$

$$\frac{\partial a_k}{\partial t} = -i \frac{\partial H_2}{\partial a_k^*}$$

$$H_2 = \int \omega_k |a_k|^2 dk$$

Nonlinearity:

$$\mathbf{k}_1 + \mathbf{k}_2 = \mathbf{k}_3 + \mathbf{k}_4$$

$$\mathbf{k} = \mathbf{k}_0 + \mathbf{q}_k, \quad q_k \ll k_0$$

$$H_4 = \dots$$

$$H = H_2 + H_4 = H_2 + \int T_{1234} a_1 a_2 a_3^* a_4^* \delta(\mathbf{k}_1 + \mathbf{k}_2 - \mathbf{k}_3 - \mathbf{k}_4) d\mathbf{k}_1 d\mathbf{k}_2 d\mathbf{k}_3 d\mathbf{k}_4$$

Rewrite $\frac{\partial a_k}{\partial t} + i\omega a_k = -i \frac{\partial H_4}{\partial a_k^*}$ for the envelope, $a_k(t) = e^{-i\omega_0 t} \psi(\mathbf{q}, t)$,

$$\frac{\partial \psi_{\mathbf{q}}}{\partial t} - i\omega_0 \psi_{\mathbf{q}} + i\omega(\mathbf{q}) \psi_{\mathbf{q}} = -iT \int \psi_1^* \psi_2 \psi_3 \delta(\mathbf{q} + \mathbf{q}_1 - \mathbf{q}_2 - \mathbf{q}_3) d\mathbf{q}_1 d\mathbf{q}_2 d\mathbf{q}_3$$

Why universal?

$$i \frac{\partial \psi_{\mathbf{q}}}{\partial t} + \omega_0 \psi_{\mathbf{q}} - \omega(\mathbf{q}) \psi_{\mathbf{q}} = T \int \psi_1^* \psi_2 \psi_3 \delta(\mathbf{q} + \mathbf{q}_1 - \mathbf{q}_2 - \mathbf{q}_3) d\mathbf{q}_1 d\mathbf{q}_2 d\mathbf{q}_3$$

Assume $\omega = \omega(k)$ and expand for small \mathbf{q}

$$\omega(\mathbf{q}) = \omega_0 + \mathbf{q}_i \left(\frac{\partial \omega}{\partial k_i} \right)_0 + \frac{1}{2} \mathbf{q}_i \mathbf{q}_j \left(\frac{\partial^2 \omega}{\partial k_i \partial k_j} \right)_0 = \omega_0 + v \mathbf{q}_{\parallel} + \frac{1}{2} \left(\omega'' q_{\parallel}^2 + \frac{v}{k_0} q_{\perp}^2 \right)$$

Back to r -space ($\mathbf{k}_0 \parallel \hat{\mathbf{z}}$):

$$i \underbrace{\left(\frac{\partial \psi}{\partial t} + v \frac{\partial \psi}{\partial z} \right)}_{\frac{\partial \psi}{\partial t} \text{ in moving frame}} + \underbrace{\frac{\omega''}{2} \frac{\partial^2 \psi}{\partial z^2}}_{\text{dispersion}} + \underbrace{\frac{v}{2k_0} \nabla_{\perp}^2 \psi}_{\text{diffraction}} = \underbrace{T |\psi|^2 \psi}_{\text{nonlinearity}}$$

Rescale ψ and spatial coordinates:

$$i \psi_t + \nabla^2 \psi \pm |\psi|^2 \psi = 0$$

Why optical?

$$\frac{1}{c^2} (\epsilon E)_{tt} - \nabla^2 E = 0$$

Stationary envelope: $E = \frac{1}{2} \psi(x, y, z) e^{ikz - i\omega t}$, with $\omega = \frac{kc}{\sqrt{\epsilon_0}}$.

Kerr nonlinearity: $\epsilon = \epsilon_0 + \epsilon_2 |E|^2 = \epsilon_0 + \epsilon_2 |\psi|^2$.

$$\frac{1}{c^2} (i\omega)^2 (\epsilon_0 + \epsilon_2 |\psi|^2) \psi - [\nabla^2 \psi + 2ik\psi_z - k^2 \psi] = 0$$

Neglecting $\frac{\partial^2 \psi}{\partial z^2}$ and using $kx \rightarrow x$, $\frac{1}{2}kz \rightarrow z$, and $\psi | \frac{\epsilon_2}{k\epsilon_0} |^{\frac{1}{2}} \rightarrow \psi$,

$$i\psi_z + \nabla_{\perp}^2 \psi + T |\psi|^2 \psi = 0, \quad \text{with } T = \pm 1$$

Collapses in focusing NSE

Integrals of motion

$$N = \int |\psi|^2 d^D r$$

$$\mathcal{H} = \int (|\nabla\psi|^2 - \frac{1}{2}|\psi|^4) d^D r$$

Within the packet

$$|\psi|^2 \sim N/L^D$$

$$\mathcal{H} \sim NL^{-2} - N^2L^{-D}$$

$$i\psi_t + \nabla^2\psi + |\psi|^2\psi = 0$$

Cascades of turbulence

$$\mathcal{H} = \int \omega_k |a_k|^2 dk$$

$$N = \int |a_k|^2 dk$$

$$N_1 + N_3 = N_2$$

$$\omega_1 N_1 + \omega_3 N_3 = \omega_2 N_2$$

$$N_1 = N_2 \frac{\omega_3 - \omega_2}{\omega_3 - \omega_1} \approx N_2$$

$$N_3 = N_2 \frac{\omega_2 - \omega_1}{\omega_3 - \omega_1} \ll N_2$$

$$\omega_1 N_1 \ll \omega_2 N_2$$

$$\omega_3 N_3 \approx \omega_2 N_2$$

Modulational instability

$$i\psi_t = -\frac{1}{2}\omega''\nabla^2\psi + T|\psi|^2\psi$$

Exact solution (condensate):

$$\Psi = \sqrt{N_0}e^{-iTN_0t}$$

For small perturbation $\psi := \Psi + \psi$,

$$i\psi_t = -\frac{1}{2}\omega''\nabla^2\psi + 2TN_0\psi + T\Psi^2\psi^* + O(|\psi|^2).$$

In k -space, using $(\psi^*)_k = \psi^*_{-k}$,

$$\begin{aligned} i\frac{d}{dt}\psi_k &= \left(\frac{1}{2}\omega''k^2 + 2TN_0\right)\psi_k + T\Psi^2\psi^*_{-k}, \\ -i\frac{d}{dt}\psi^*_{-k} &= \left(\frac{1}{2}\omega''k^2 + 2TN_0\right)\psi^*_{-k} + T\Psi^2\psi_k. \end{aligned}$$

Modulational instability

Looking for the solution in the form

$$\psi_k = \alpha e^{-i(TN_0 + \Omega_k)t} \quad \text{and} \quad \psi_{-k}^* = \beta e^{i(TN_0 - \Omega_k)t},$$

rewrite the system as

$$\begin{pmatrix} \frac{1}{2}\omega''k^2 + TN_0 - \Omega_k & T\Psi^2 \\ T\Psi^{*2} & \frac{1}{2}\omega''k^2 + TN_0 + \Omega_k \end{pmatrix} \begin{pmatrix} \alpha e^{-iTN_0t} \\ \beta e^{iTN_0t} \end{pmatrix} = 0$$

Bogoliubov dispersion relation:

$$\Omega_k^2 = \omega'' TN_0 k^2 + \frac{1}{4}\omega''^2 k^4$$

Instability: $\omega'' T < 0$ (focusing nonlinearity).

Why turbulence?

- ▶ Wide energy spectra; cascades
- ▶ Statistical description
- ▶ High probability of extreme events (intermittency)
- ▶ Coherent structures — condensate or collapses
- ▶ Steady (with damping/forcing) or decaying

The rest of this talk is restricted to steady NSE turbulence in 2D.

Defocusing nonlinear Schrödinger equation

$$i\psi_t + \nabla^2\psi - |\psi|^2\psi = i\hat{f}\psi$$

Condensate

$$\Psi = \sqrt{N_0} \exp(-iN_0 t)$$

Notation:

$$N = |\overline{\psi}|^2$$

$$N_0 = |\overline{\psi}|^2$$

$$n = N - N_0 = \int |\psi_k|^2 d^2k$$

We consider large condensate

$$N_0 \gg n$$

Statistically quasi-steady

$$t \sim 10^4 \gg \frac{1}{\omega} \sim 10^{-3}$$

Onset of condensate

$t = 100$: $N_0 = 58$, $n = 160$

$t = 1500$: $N_0 = 751$, $n = 20$

amplitude

Phase transitions: breakdown of symmetries

- ▶ Higher condensate \Rightarrow more ordered system
- ▶ Long-range orientational, short-range positional order
- ▶ What happens at even larger N ?

Effect of forcing

Instability-driven force

$$i\psi_t + \nabla^2\psi - |\psi|^2\psi = i\hat{f}\psi$$

Random force

$$i\psi_t + \nabla^2\psi - |\psi|^2\psi = i\hat{F}$$

Small perturbations

Compare quadratic and cubic terms in Hamiltonian

$$\begin{aligned}
 \langle \mathcal{H}_2 \rangle &= \Omega_k n = N_0^{1/2} k n \\
 \langle \mathcal{H}_3 \rangle &= \sum_{\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3} V_{123} \langle \psi_{\mathbf{k}_1} \psi_{\mathbf{k}_2} \psi_{\mathbf{k}_3}^* \rangle \delta(\mathbf{k}_1 + \mathbf{k}_2 - \mathbf{k}_3) \\
 &\simeq \sum_{\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3} |V_{123}|^2 n_1 n_2 \delta(\mathbf{k}_1 + \mathbf{k}_2 - \mathbf{k}_3) \delta(\Omega_1 + \Omega_2 - \Omega_3) \\
 &\simeq \frac{|V|^2 n^2 c}{k^3} \frac{k}{c} \simeq \frac{n^2 k}{N_0^{1/2}}
 \end{aligned}$$

Effective nonlinearity parameter is small,

$$\frac{\mathcal{H}_3}{\mathcal{H}_2} \simeq \frac{n}{N_0}.$$

But: weak turbulence assumes random phases.

Angle of interaction: $k/c \sim k/\sqrt{N_0}$, where $c = \sqrt{2N_0}$.

Angle of interaction

 $N_0 = 400$  $N_0 = 3600$ 

Arch grows in k -space from the condensate to a preset mode, \mathbf{k}_0 .

Arch equation:

$$\omega(k_0) = \omega(k) + \omega(|\mathbf{k}_0 - \mathbf{k}|)$$

$$\omega^2(k) = 2N_0k^2 + k^4$$

Angle of interaction:

$$\phi_{max} \approx \frac{k}{\sqrt{3N_0/2}} \sim \frac{k}{c}$$

Phase coherence

n_k

$$\theta_k = 2\phi_0 - \phi_k - \phi_{-k}$$

$$2\phi_0 - \phi_k - \phi_{-k} = \pi$$

Three-wave model

Consider condensate interacting with two waves

$$\psi_{\pm k} = \sqrt{n} \exp(\pm ikx + iN_0 t + i\phi_{\pm k})$$

with $\theta = 2\phi_0 - \phi_k - \phi_{-k}$.

Hamiltonian:

$$H = 2k^2 n + \frac{1}{2} N^2 + 2n(N - 2n)(1 + \cos\theta) + n^2$$

Equations of motion:

$$\begin{aligned} \dot{n} &= 2n(N - 2n) \sin\theta \\ \dot{\theta} &= 2k^2 + 2(N - 3n) + 2(N - 4n) \cos\theta \end{aligned}$$

Stability points:

$$\begin{aligned} \theta = \pi, \quad n = -\frac{1}{2}k^2 &\Rightarrow \text{unphysical} \\ \theta = 0, \quad n = (4N + k^2)/14 &\Rightarrow \text{too high } n \end{aligned}$$

Predictions of three-wave model

$$\dot{n} = 2n(N - 2n) \sin \theta$$

$$\dot{\theta} = 2k^2 + 2(N - 3n) + 2(N - 4n) \cos \theta$$

For $n \ll N$:

- ▶ the system spends most of its time around $\theta = \pi$ state
- ▶ the frequency of oscillations $2\Omega \approx 2\sqrt{2Nk^2 + k^4}$
- ▶ the amplitude $a \equiv \sqrt{n(t)}$ exhibits complicated cusped shape

Individual modes in turbulence

In turbulence, $n \ll N$ condition is well satisfied.

As predicted:

- ▶ the system spends most of its time around $\theta = \pi$ state
- ▶ the frequency of oscillations approaches $2\Omega = 2\sqrt{2Nk^2 + k^4}$
- ▶ the amplitude $a \equiv \sqrt{n(t)}$ exhibits complicated cusped shape

However:

The 3-wave model cannot grasp closed trajectories with $\theta \approx \pi$.

Collective oscillations

- ▶ The system periodically oscillates around a steady state.
- ▶ Turbulence and condensate exchange a small fraction of waves.
- ▶ The condensate imposes the phase coherence between the pairs of counter-propagating waves (anomalous correlation).
- ▶ Collective oscillations are not of a predator-prey type; they are due to phase coherence and anomalous correlations.

Focusing nonlinear Schrödinger equation

$$i\psi_t + \nabla^2\psi + |\psi|^2\psi = 0$$

$$i\psi_t + (1 - i\epsilon a)\nabla^2\psi + (1 + i\epsilon c)|\psi|^2\psi = i\epsilon b\psi$$

Can we explain the statistics of a turbulent field with statistics and properties of individual collapses?

Distribution of $|\psi|$ in the field

Notation: $h \equiv |\psi|$, $h_{avg} = \langle |\psi| \rangle \propto \sqrt{N}$, $N = \int |\psi|^2 d^2r$.

Turbulent background:

- ▶ is well described by h_{avg}
- ▶ what determines h_{avg} ?

Collapse contribution:

- ▶ power-law (?) for $h \gg h_{avg}$
- ▶ depend on a, c but not b

Catastrophic collapse

Townes soliton, $\psi = \frac{1}{L} e^{i\omega t} R(\rho)$, with $\rho = \frac{r}{L}$, $\omega = \frac{1}{L^2}$

$$i\psi_t + \nabla^2 \psi + |\psi|^2 \psi = 0 \quad \Rightarrow \quad \boxed{R'' + \frac{1}{\rho} R' = R - R^3.}$$

Unstable: if $N > N_c$, the soliton blows up in finite time, t_c .

Collapsing solution is self-similar and rescales to Townes soliton.

Lens transform maps $t_c \rightarrow \infty$.

What is the functional form of $L(t)$?

Lens transform

In slow variables, $\rho = \frac{r}{L}$ and $\tau = \int L^{-2}(t')dt'$, look for solution

$$\psi(r, t) = \frac{1}{L} V(\rho, \tau) e^{i\tau + i\gamma(\tau)\rho^2/4}$$

$V(\rho, \tau)$ is real when $\gamma = LL_t$. Using $\beta \equiv -L^3 L_{tt}$ we get,

$$\underbrace{iV_\tau}_{\text{neglect}} + \nabla^2 V + V^3 - V + \frac{1}{4}\beta\rho^2 V = 0.$$

β is the measure of excess of N over critical, $\nu(\beta)$ is the loss rate.

Using β as a small parameter,

$$\begin{aligned} L_{\tau\tau} - 2L_\tau^2/L &= -\beta L && \text{small scales} \\ \beta_\tau &= -\nu(\beta) && \text{large scales} \end{aligned}$$

Loglog scaling at $t \rightarrow t_c$

$$L \sim \left[\ln \ln \frac{1}{t_c - t} \right]^{-\frac{1}{2}} (t_c - t)^{\frac{1}{2}}$$

Loglog and early evolution bridged!

$L(t)$ depends on N

$\beta_\tau(\beta)$ is universal

Loglog law: $t \rightarrow t_c$.

Adiabatic approximation, $\beta = const$: short times or small β .

New approximation for $\nu(\beta)$ accounts for initial excess of N and bridges early evolution and loglog asymptotics.

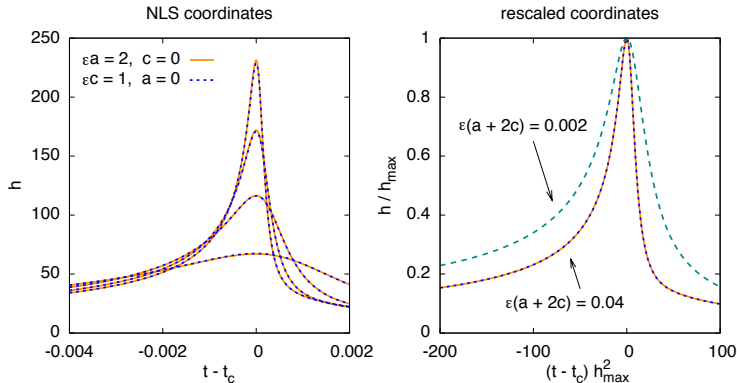

Collapses with stabilization

$$i\psi_t + (1 - i\epsilon a)\nabla^2\psi + (1 + i\epsilon c)|\psi|^2\psi = i\epsilon b\psi$$

Growth: $L \propto (t_c - t)^\alpha$, $\alpha \approx \frac{1}{2}$, rate depends on a and c .

Decay: $L \propto (t - t_c)^{-1}$, Talanov solution, unstable.

Rescaled evolution: $(a + 2c)$ similarity

Growth and saturation of a collapse is controlled by $a + 2c$ combination.

From direct integration of NSE,

$$N_t = -2\epsilon(aH_k - 2cH_p - bN), \quad \text{where} \quad H_k + H_p = H.$$

For critical collapse: $\psi = e^{i\omega t} u(r)$, $H_k = -H_p = \omega N_c$, $\omega = h^2$

$$N_t = -2\epsilon(a + 2c)h^2 N_c$$

ODE model for collapse saturation

$$L^2 \beta_t = -k_1 - k_2 \beta + k_3 (LL_t)^2 - \nu(\beta)$$

$$L^3 L_{tt} = -\beta$$

$$k_1 \approx 6.76 \epsilon(a+2c), \quad k_2 \approx 2.01 \epsilon a, \quad k_3 \approx 0.01 \epsilon a.$$

Data suggest: k_1 term describes first order effects well;
 $k_2 \approx -37\epsilon(a+2c)$ instead of original $k_2 \approx 2\epsilon a$.

Universality of collapses in turbulence

Connecting PDF of $|\psi|$ to frequency of collapses

- ▶ Assume similarity among collapses, $h \sim (t_c - t)^{-\frac{1}{2}}$.
- ▶ Left: frequency of collapses with $h > h_{\max}$ per unit area.
- ▶ Right: solid lines show $F(h_{\max})$; points show $0.012 h^5 P(h)$.
- ▶ Conclude that PDF in the field $P(h) \sim h^{-5} F_{\max}(h)$.

Distribution of $|\psi|$ in the field

turbulent background

collapse contribution

A lot about focusing NSE turbulence not understood yet:

- ▶ universality of the background
- ▶ how collapses are seeded
- ▶ how breaking of collapses contribute to turbulence
- ▶ how saturation parameters affect the system

Conclusion

References

Conclusion

- ▶ The nonlinear Schrödinger equation is a universal model, describing a spectrally narrow wave packet.
- ▶ Focusing and defocusing nonlinearities exhibit different behavior.
- ▶ In 2D, focusing nonlinearity results in collapses.
- ▶ In 2D, defocusing nonlinearity results in condensate.
- ▶ Interaction of either collapses or condensate with background turbulence is nontrivial.
- ▶ The study of NSE turbulence has just begun...
