Recall that a variable has the following characteristics

- 1 name
- 2 address
- 3 value
- 4 type

How can we obtain the address of a variable?

By using the 'Address Of' operator **&**

ILLUSTRATION:

```
1 #include <stdio.h>
2
3 int main()
4 {
5     float X = 302.45;
6
7     printf(" Value of X = %f\n",X);
8     //Use of Address Of operator &
9     printf("Memory Address of X = %p\n",&X);
10
11 }
```

Given a memory address, how do we determine the value at that location?

By using the 'Value At Address' Or Indirection operator *

ILLUSTRATION:

```
1 #include <stdio.h>
2
3 int main()
4 {
5     float X = 302.45;
6     //The usual way
7     printf("Value of X = %f\n", X);
8     //The use of the 'Value At Address' operator
9     printf("Value of X = %f\n", *(&X) );
10
11
12 }
```

A **POINTER** is a variable that holds memory address values.

Since a pointer is still a **variable**, the following characteristics still apply.

- 1 name
- 2 address
- 3 value
- 4 type

The **type** a of pointer determines the kind of address it can store. For example, if we say a pointer is of type **int**, then only the memory address of integer variables can be stored by the pointer.

Syntax: Declaration of a Pointer

```
data_type * pointer_name;
```

```
//declare an integer pointer  
int*iPtr;
```

```
//declare a character pointer  
char * pointer;
```

```
//declare a float pointer  
float *direct;
```

```
//declare a pointer to an integer pointer  
int ** k;
```

```
1 #include <stdio.h>
2
3 int main()
4 {
5     int i = 200;    //integer variable
6     int * j;        //integer pointer
7     int ** k;       //pointer to an integer pointer
8
9     j=&i;            //assign address of i to j
10    k=&j;             //assign address of j to k
11
12    printf("Addr. of i = %p\n",&i);
13    printf("Addr. of i = %p\n",j);
14    printf("Val. of i = %d\n",i);
15    printf("Val. of i = %d\n",*(&i));
16    printf("Val. of i = %d\n",*j);
17    printf("Val. of i = %d\n",**k);
18
19 }
```

Value

PASS BY VALUE Copies of values of actual arguments are passed on to their corresponding formal arguments during function invocation.

Example

```

1 #include <stdio.h>
2 void swap(int , int);
3 int main()
4 {
5     int i=5;
6     int j=10;
7     printf("\n\n main :: Before swap: i = %d, j = %d", i, j);
8     swap(i, j);
9     printf("\n\n main :: After swap: i = %d, j = %d\n", i, j);
10 }
11
12 void swap(int a, int b)
13 {
14     int tmp;
15     printf("\n\n swap :: Before swap: a = %d, b = %d", a, b);
16     tmp=a;
17     a=b;
18     b=tmp;
19     printf("\n\n swap :: After swap: a = %d, b = %d", a, b);
20 }

```

Reference

PASS BY REFERENCE Addresses of actual arguments are passed on to their corresponding formal arguments during function invocation.

Example

```

1 #include <stdio.h>
2 void swap(int*, int*);
3 int main()
4 {
5     int i=5;
6     int j=10;
7     printf("\n\n main :: Before swap: i = %d, j = %d", i, j);
8     swap(&i, &j);
9     printf("\n\n main :: After swap: i = %d, j = %d\n", i, j);
10 }
11
12 void swap(int * a, int * b)
13 {
14     int tmp;
15     printf("\n\n swap :: Before swap: a = %d, b = %d", *a, *b);
16     tmp=*a;
17     *a=*b;
18     *b=tmp;
19     printf("\n\n swap :: After swap: a = %d, b = %d", *a, *b);
20 }

```

Expressions

Pointers can be used in arithmetic expression as illustrated below: **Example**

```

1 #include <stdio.h>
2
3 int main()
4 {
5     int x=200;
6     int y=400;
7     int * ptrX;
8     int * ptrY;
9
10    ptrX=&x;
11    ptrY=&y;
12
13    printf("\nx + *ptrX = %d", x + *ptrX);
14    printf("\ny - *ptrY = %d", y - *ptrY);
15    printf("\n5 * *ptrX - *ptrY = %d", 5* *ptrX - *ptrY);
16    printf("\n*ptrX * *ptrY = %d", *ptrX * *ptrY);
17    printf("\n*ptrY / *ptrX = %d\n", *ptrY / *ptrX);
18 }
```

Suppose p,q and r are integer pointers

Suppose x,y and z are char pointers

- 1 When we increment a pointer, its value is increased by the length of the data type it points to.
 - char (1 byte)
 - integer (4 bytes) 32 bit word computer
 - float (4 bytes)
 - double (8 bytes)
- 2 The length is referred to as the **scale factor**

Pointers & Arrays

The address of the first element of an array is called the **Base Address**

The base address of an array may be assigned to a pointer in two way:

```
1 int marks[5];
2 int * ptr;
3
4 //Assign base address of marks to ptr
5 ptr=&marks[0];
6
7 //Alternatively , assign base address of marks to ptr
8 ptr=marks;
```

Example of Pointers and Arrays

```
1 #include <stdio.h>
2
3 int main()
4 {
5     int marks[5]={ 30,20,70,25,55};
6     int * ptr;
7     int i=0;
8
9     //assign base address of marks to ptr
10    ptr=marks;
11
12    for ( i=0;i <5;i++)
13    {
14        printf("@ %u: marks[%d] = %d\n", (ptr+i), i,
15
16    }
17 }
```

QUESTION 1 :

With reference to question 1 on arrays, previously discussed, where you find f_x values for given x , write a C code that has a void function called swap that uses pointer(s) to swap the values of x and f_x and prints the results to screen.

The swap function should take two arguments:

```
swap(int * a, int * b)
```

Special thanks to the following for their initial work:
