

Other things you might want to know about Isca (FAQs) - ICTP day 2

Dr Stephen I. Thomson

Some little things

- In the **submission** scripts, there is an option to provide an email address.
 - Argo will email you when the job starts and when it finishes (can be useful)
- I have added the lecture notes from yesterday to the `ictp-isca-workshop-2018` repository. Download it from GitHub if you like.
- **How long will the model take to run my experiment?**
- **How does the model know to run one month at a time?**
- **How is the fortran code structured? (What subroutine is calling what?)**
- **What is 'spin-up'?**
- **How do I know whether I have seasons or not?**
- **How do I know whether it's an aquaplanet or not?**
 - **How do I add land?**

- **How does the model know to run one month at a time?**

- Yesterday, I said the model runs one month at a time.
- How does it know to do that?

```
'main_nml':{  
  'days' : 30,  
  'hours' : 0,  
  'minutes': 0,  
  'seconds': 0,  
  'dt_atmos':720,  
  'current_date' : [1,1,1,0,0,0],  
  'calendar' : 'thirty_day'  
},
```

Tells model to run for 30 days

360-day calendar (30 day months)

Each time 'run' command is executed, it runs for the number of days defined in 'main_nml'

```
exp.run(1, use_restart=False, num_cores=NCORES)
```

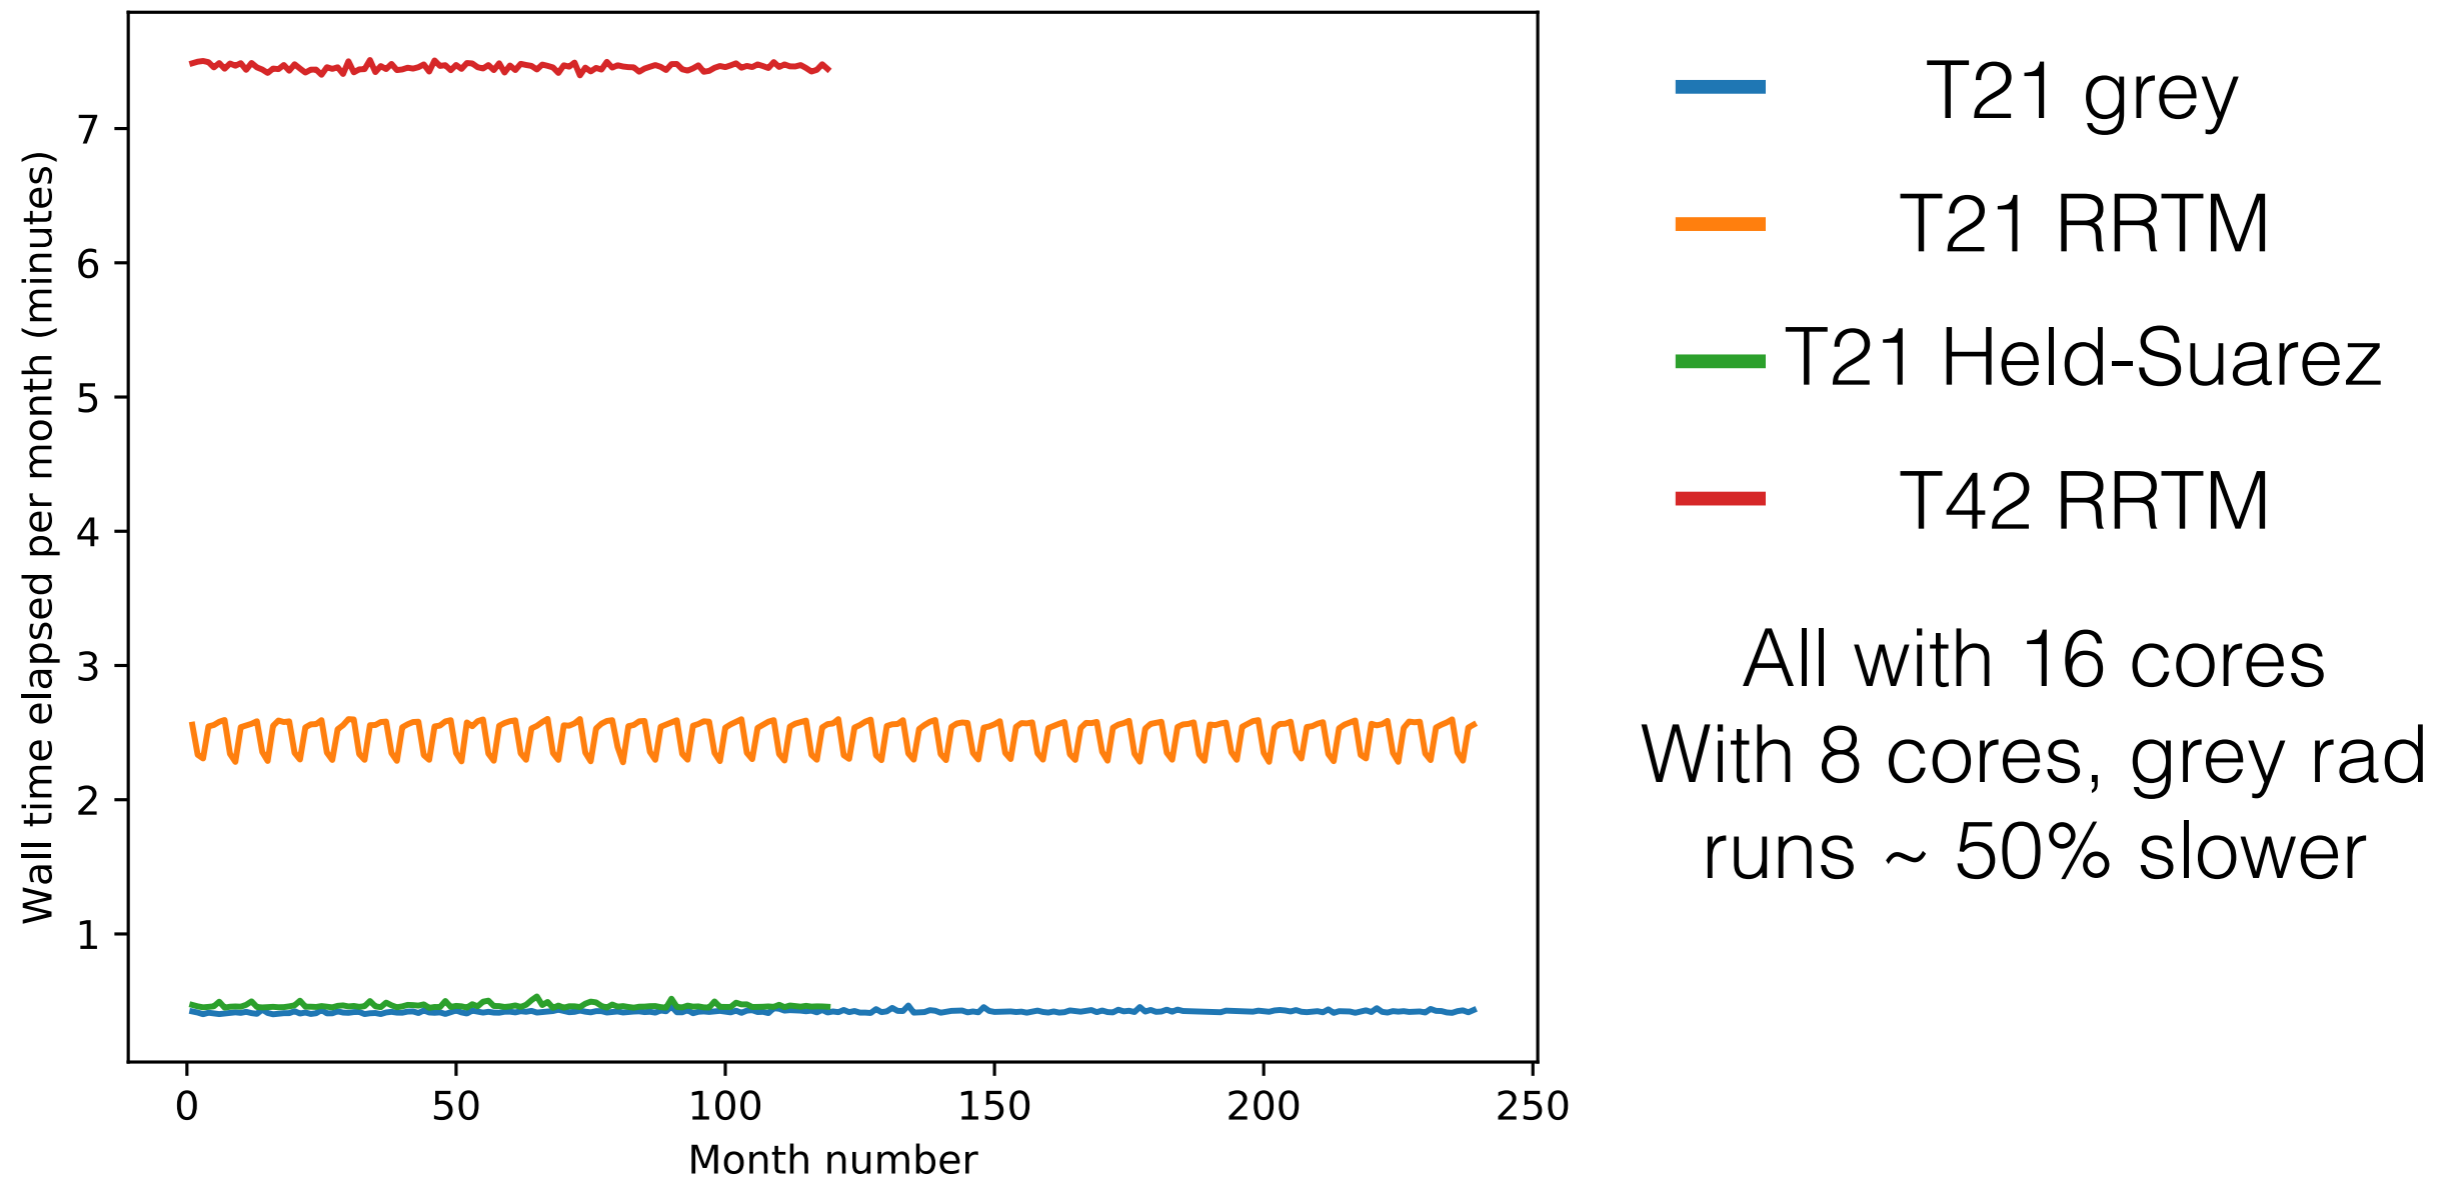

```
for i in range(2,241):
```

Runs for 240 sets of N days

```
  exp.run(i, num_cores=NCORES)
```

- **How long will the model take to run my experiment?**

`Isca/src/extra/python/scripts/modified_time_script.py`

Add your experiment folder names to the 'exp_dir_list' near the bottom of the script, then run with python.

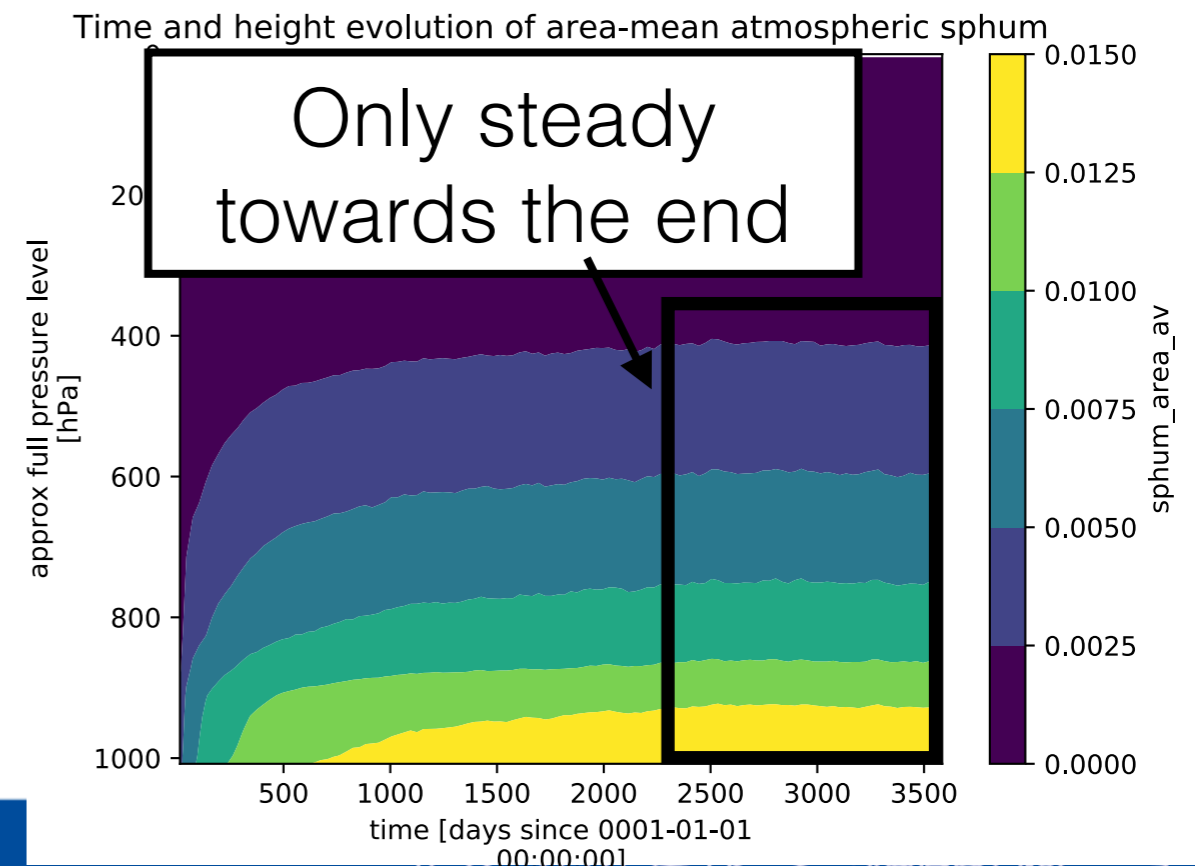

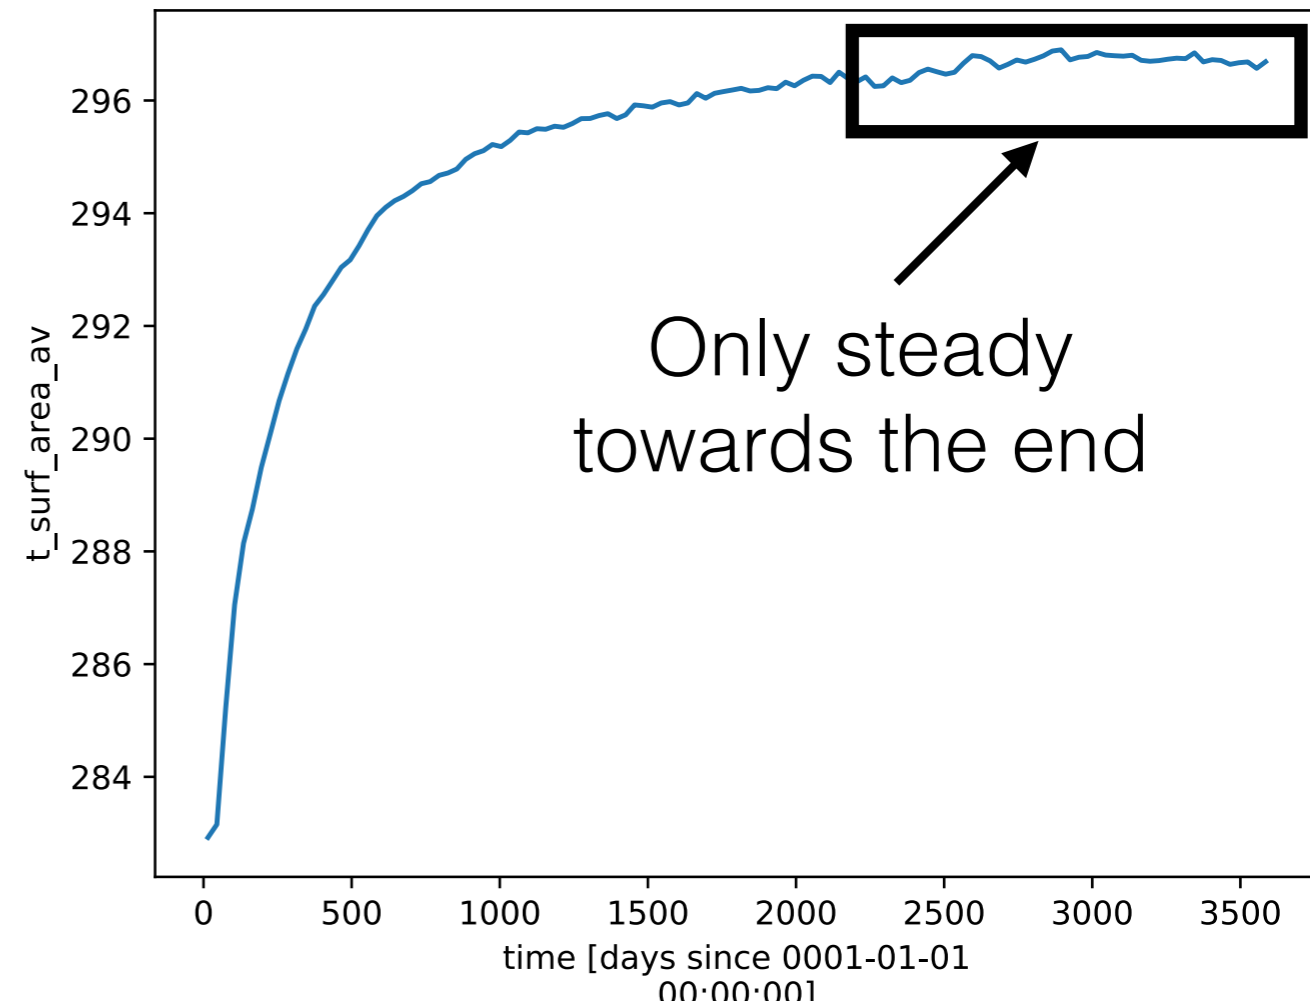

- **How is the Fortran code structured?**
- In Isca repo on the 'pre_ictp_mods' branch, there is an Excel document called 'Isca_fortran_code_structure.xlsx'.
- It shows you a simple representation of the code structure:
 - Which subroutines are calling which subroutines
 - A simple explanation of what each subroutine does...

Atmos_model	<i>atmos_model.F90</i>		
	atmosphere	<i>atmosphere.f90</i>	
		idealized_moist_phys	<i>idealized_moist_phys.F90</i>
			qe_moist_convection <i>qe_moist_convection.F90</i>
			lscale_cond <i>lscale_cond.F90</i>
			two_stream_gray_rad_down <i>two_stream_gray_rad.F90</i>
			surface_flux <i>surface_flux.F90</i>
			mo_drag <i>monin_abukhov.F90</i>
			two_stream_gray_rad_up <i>two_stream_gray_rad.F90</i>
			vert_turb_driver
			diffusivity <i>diffusivity.F90</i>
			pbl_depth <i>diffusivity.F90</i>
			diffusivity_pbl <i>diffusivity.F90</i>
			gcm_vert_diff_down <i>vert_diff.F90</i>
			mixed_layer <i>mixed_layer.F90</i>
			spectral_dynamics <i>spectral_dynamics.F90</i>
			compute_pressures_and_heights <i>press_and_geopot.F90</i>
			spectral_diagnostics <i>spectral_dynamics.F90</i>

What is spin-up?

- The model will start from a resting state - will take some time to reach equilibrium.
- Can check this with the time-variation with my analysis scripts. For example,
 - `af.global_average_lat_lon(datas et, 't_surf')`
 - `dataset.t_surf_area_av.plot.line()`
- When does it reach a steady state, or a steady seasonal cycle?

• How do I know whether I have seasons or not?

Example experiments:

- Project 1 - Seasons
- Project 2 - No seasons
- Project 3 - No seasons
- Project 4 - Seasons
- Project 5 - No seasons
- Project 6 - Seasons
- Project 7 - No seasons
- Project P1 - No seasons
- Project P2 - No seasons

```
'rrtm_radiation_nml': {  
    'do_read_ozone': True,  
    'ozone_file': 'ozone_1990',  
    'solr_cnst': 1360., #s set  
    'dt_rad': 4320, #Use 4320  
    'solday': 90,  
},
```

- If solday=90 is set, then it tells the radiation to run day 90 insolation every day (equinox)
- Same in grey and RRTM namelists
- If solday is not set, then you'll have seasons
- To add seasons, remove the solday namelist entry

- **How do I know whether it's an aquaplanet or not?**
 - By default, Isca has no land - is an aquaplanet
 - In the `mixed_layer.f90` `land_option='none'` is default
- **How do I add land?**
 - Look at e.g. project 3, as it has land
 - Step 1: Add a land mask to the 'input_files' list near the top of your run script
 - Step 2: Include the namelist entries with 'land' in the name in the relevant namelists
 - 3 in 'idealized_moist_phys_nml', 3 in 'mixed_layer_nml'
 - Step 3: add 'ocean_topog_smoothing':0.8 to 'spectral_dynamics_nml'
 - Step 4: Add the 'spectral_init_cond_nml' namelist as part of your namelist (this will add topography to the model)

- The factors that set the land-sea contrast are:
 - ‘land_roughness_prefactor’ - how much rougher is the land than the ocean?
 - ‘land_h_capacity_prefactor’ - how much lower is the land’s heat capacity than the ocean?
 - ‘land_albedo_prefactor’ - how much greater is the land albedo than the ocean albedo?
- The real-world land masks are provided in the Isca repo in [Isca/input/land_masks](#)
- If you want to make idealised land / topography - talk to me and I’ll show you how.

What about the output?

- The atmospheric output data is provided on so-called '**sigma levels**' (terrain-following coordinates)
- $\sigma = \text{atmospheric_pressure} / \text{surface_pressure}$
- On an **aquaplanet**, there's very little difference
- Makes a big difference with topography...
- If your simulation has topography, you'll need to interpolate the data onto pressure levels before analysing it - talk to me and I'll show you how.

A quick note on q-fluxes

- The evolution equation for the mixed-layer temperature is the following:

$$C_m \frac{\partial T}{\partial t} = SW + LW - \text{sensible} - \text{latent} + \nabla \cdot \mathbf{Q}$$

- In 'mixed_layer.f90' this looks like:

```
corrected_flux = - net_surf_sw_down - surf_lw_down + alpha_t * CP_AIR + alpha_lw - ocean_qflux
```

- So 'ocean_qflux' actually corresponds to $\nabla \cdot \mathbf{Q}$
- So your 'ocean_qflux' field should **integrate to zero over the globe**, because the area integral of a divergence is zero
- The q-flux input files I have given you will integrate to zero
- But **be careful if you add land that this remains true**, otherwise you'll have a net source or sink of energy in the mixed-layer.
