

EU ADVANCED COURSE IN
COMPUTATIONAL NEUROSCIENCE
An IBRO Neuroscience School

(30 July - 24 August 2001)

*"Models of Subthalamo-Pallidal
Oscillations and their Suppression"*

presented by:

Charles J. WILSON

University of Texas at San Antonio

Division of Life Sciences

6900 N. Loop, 1604 W.

San Antonio, TX 78249

U.S.A.

These are preliminary lecture notes, intended only for distribution to participants.

C. J. Wilson

Models of subthalamo-pallidal oscillations
and their suppression.

Figure 1 Schematic diagram of the basal-ganglia- thalamocortical circuitry under (a) normal conditions, as well as in (b) parkinsonism and (c) Huntington's disease. Normal neuronal activity is depicted as medium gray (a); increased activity is shaded dark gray and decreased activity is shaded light gray (b, c). Inhibitory connections are depicted as black arrows, and excitatory connections as white arrows. Both disease states lead to differential changes in the two striato-pallidal projections, which are indicated by the thickness of the connecting arrows. In parkinsonism, basal ganglia output to the thalamus (i.e. GPi/SNr to VL) is increased, whereas it is decreased in Huntington's disease. D, direct pathway (putamen to GPi/SNr); D1 and D2, dopamine receptors; I, indirect pathway (putamen to GPe/STN/GPi/SNr).

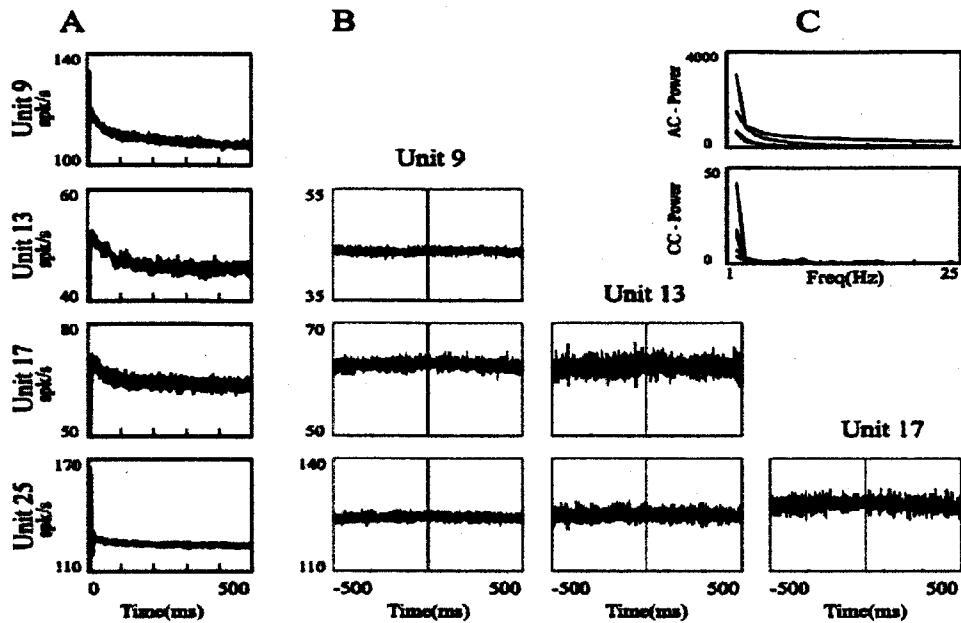

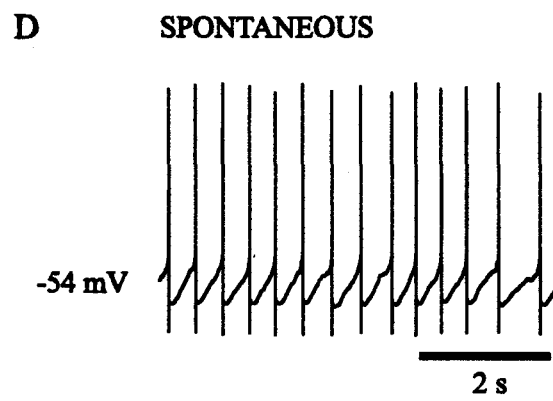

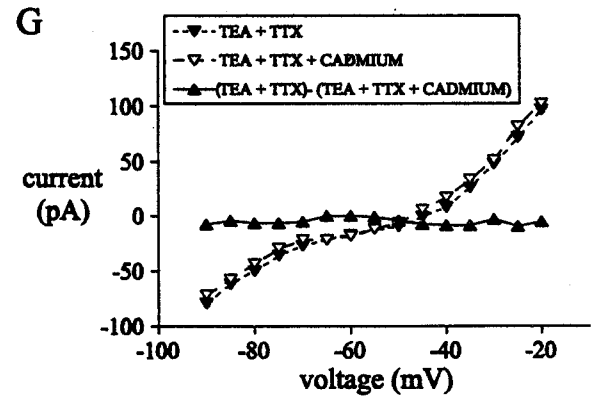

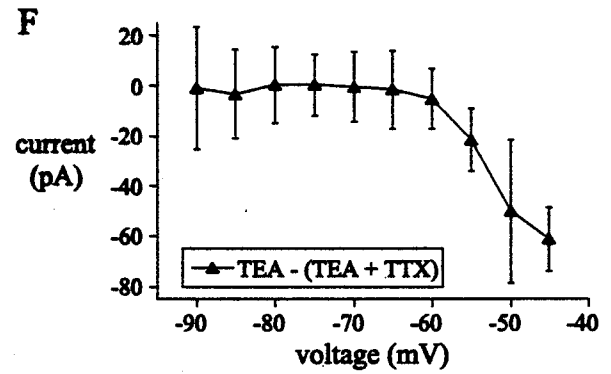

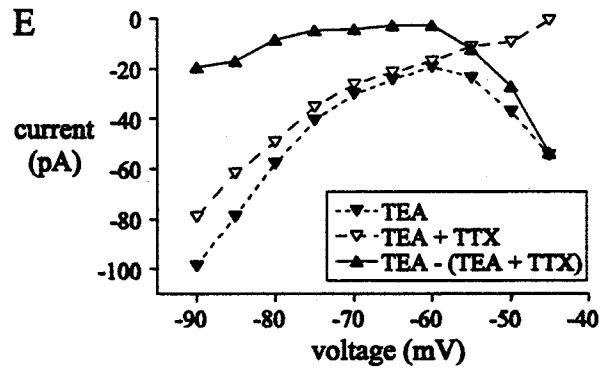

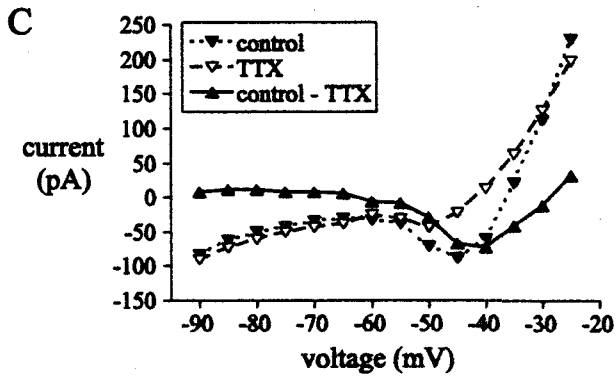

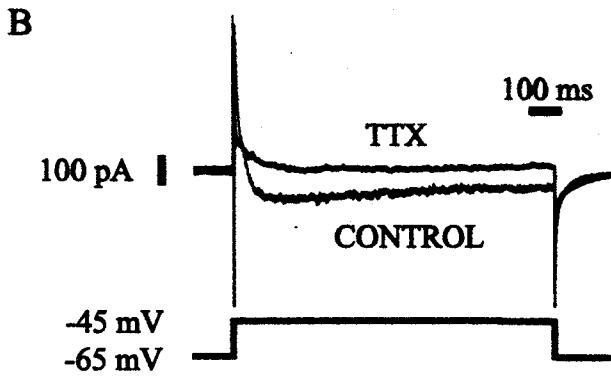

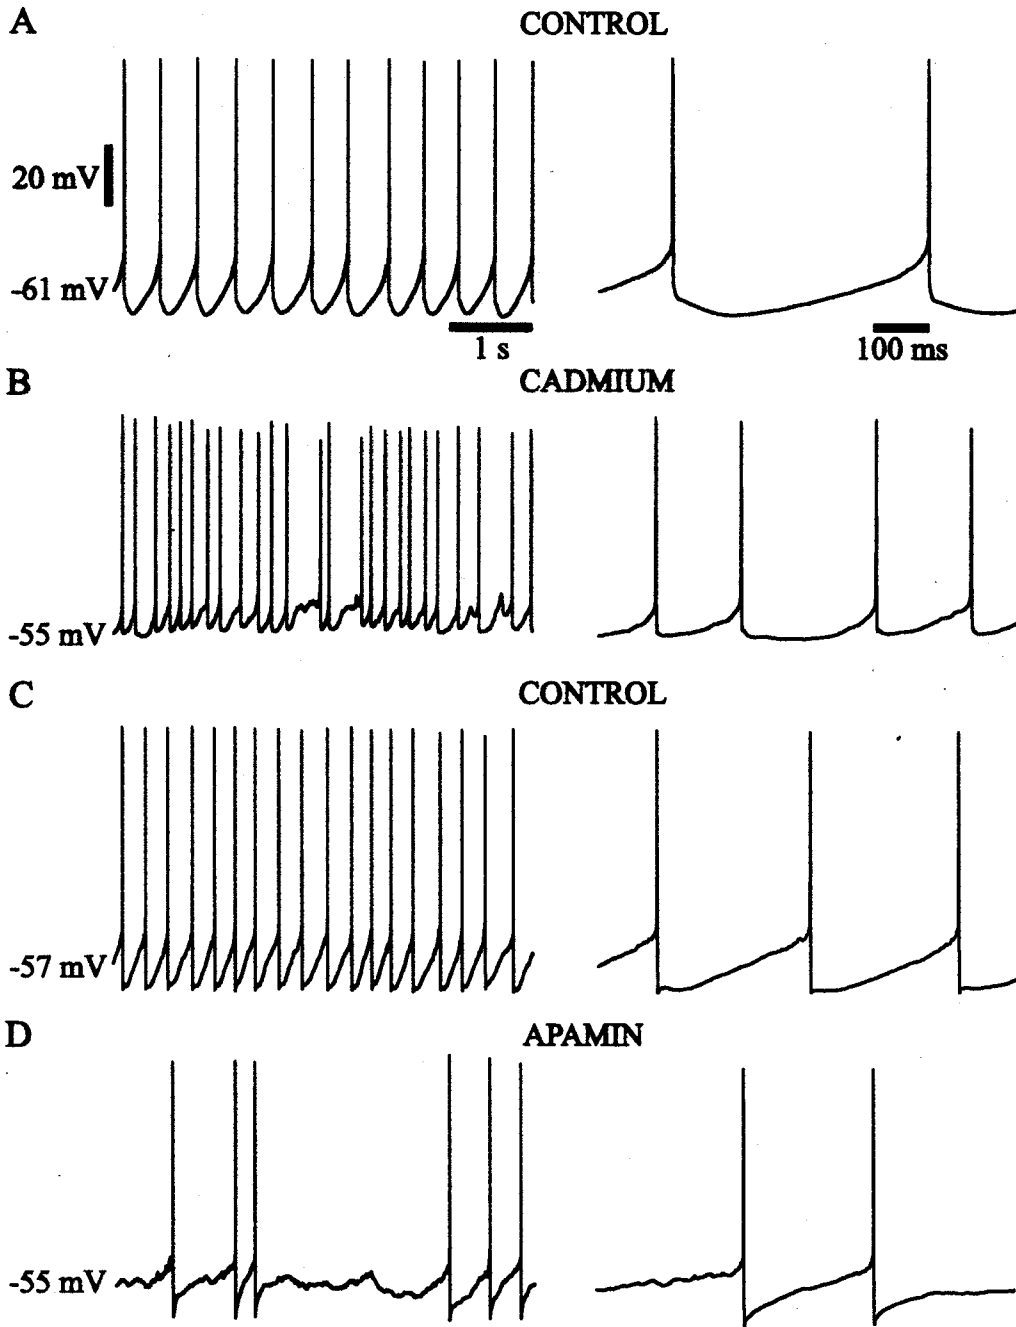

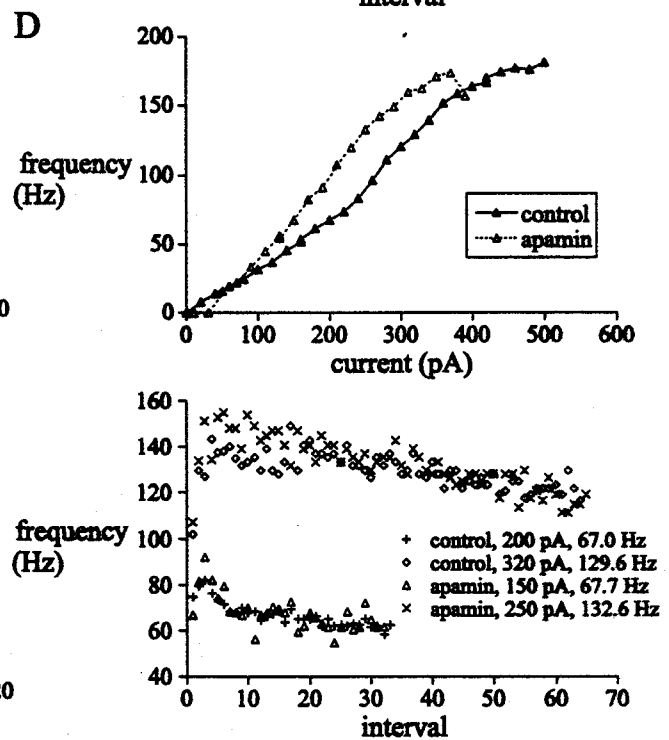

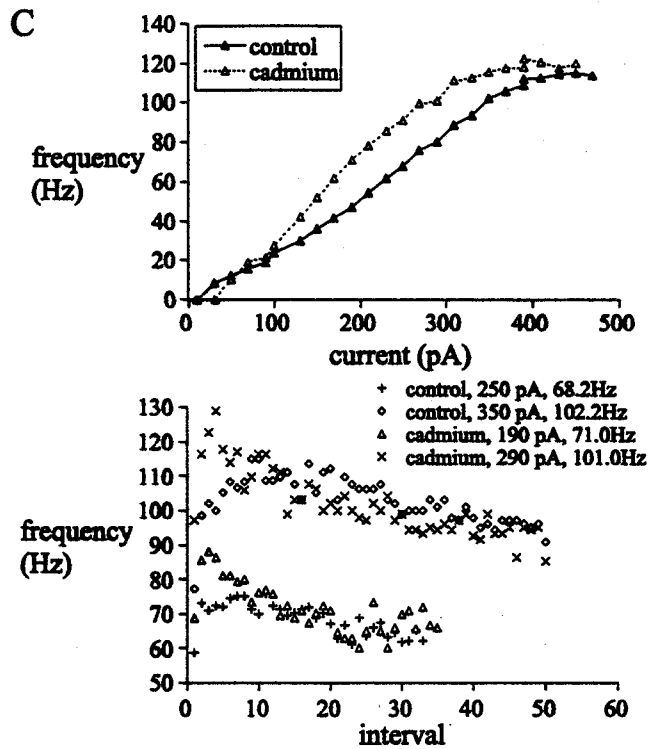

Figure 12. Auto- and cross-correlograms with power spectra of GP cells in a normal monkey. **A**, Autocorrelograms. **B**, Cross-correlation matrix. Identification of the trigger unit appears at the top, and identification of the reference unit appears at the left. Bin size was 1 msec, and no smoothing was performed. The y-axis displays conditional firing rate. **C**, Power spectra of all the autocorrelograms (top) and cross-correlograms (bottom). Cells 9 (Unit 9) and 17 (Unit 17) were from the GPe, and cells 13 (Unit 13) and 25 (Unit 25) were from the GPi. AC, Autocorrelograms; CC, cross-correlograms.

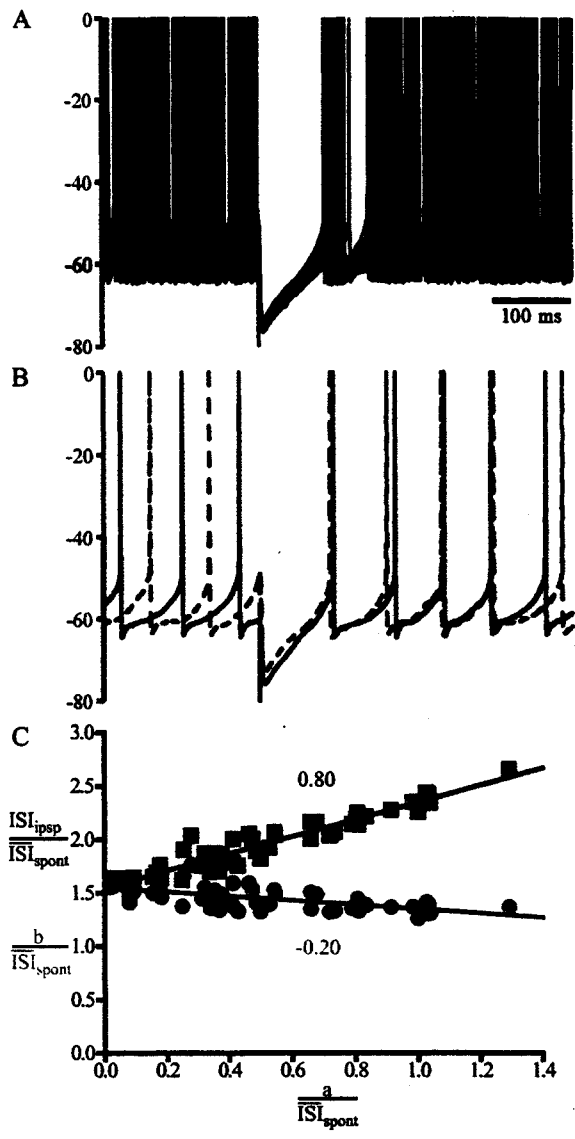

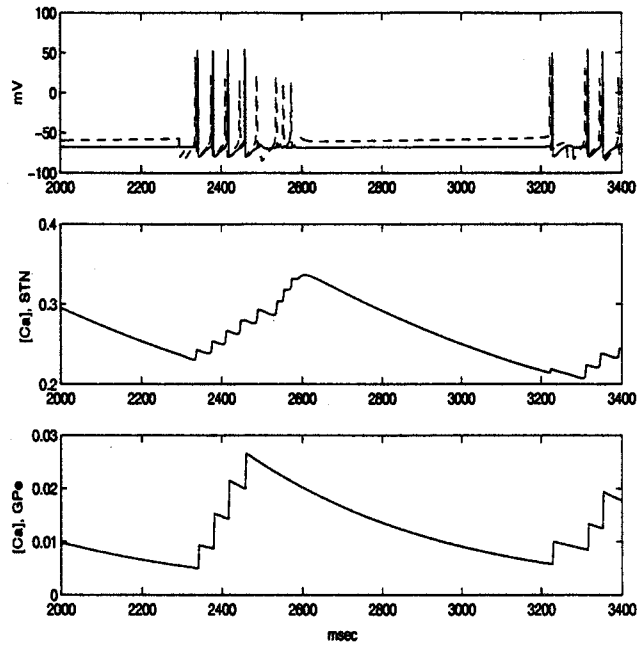

a) calcium drives mechanism for episodic activity

b) T-current drives mechanism for clustered activity
