**In metals, a ripple structure has been
never observed, but only pits and holes
reflecting the surface symmetry**

- ⇒ Pt(111), Michely & Comsa (1993)
- ⇒ Cu(111), Naumann et al. (1997)
- ⇒ Cu(001), Ritter et al. (1996)
- ⇒ Fe films, Krim et al. (1993)

**This difference is due to the prevalence of the
smoothing terms (i.e. diffusion terms) and then
it should be possible to induce a ripple structure
by lowering the temperature**

SELF SIMILARITY

One object can be self-similar if it is formed by parts that are "similar" to the whole.

Deterministic fractal

Many objects existing in nature are random. Despite this randomness such objects may be self-similar in a statistical sense.

Statistical fractal

If the scale transformation is isotropic

Self similar - fractal

Fractal objects that must be rescaled using an anisotropic transformation are

Self-affine fractal

$$\frac{\partial h(\vec{x}, t)}{\partial t} = \nu \nabla^2 h + \eta(\vec{x}, t)$$

Edwards-Wilkinson
equation -

$$\vec{x} \rightarrow \vec{x}' \equiv b\vec{x}$$

$$h \rightarrow h' \equiv b^\alpha h$$

$$t \rightarrow t' \equiv b^\beta t$$

$$\frac{\partial h}{\partial t} = \nu b^{\alpha-2} \nabla^2 h + b^{-\frac{\alpha}{2} - \frac{\beta}{2} - \alpha}$$

$$\alpha = \frac{2-d}{2}$$

$$\beta = \frac{2-d}{4}$$

$$z = 2$$

Once we obtain a growth equation we must find its predictions determining the scaling exponents and scaling functions.

If the growth process is described by a sufficiently simple equation we can solve it exactly.

However for many equations no exact solutions exist so we must apply various approximations to uncover

the scaling behavior.

RENORMALIZATION GROUP METHOD.

Stochastic Model for Surface Erosion via Ion Sputtering: Dynamical Evolution from Ripple Morphology to Rough Morphology

Rodolfo Cuerno,¹ Hernan A. Makse,¹ Silvana Tomassone,² Stephen T. Harrington,¹ H. Eugene Stanley¹

²Physics Department, Northeastern University, Boston, Massachusetts 02115
 (Received 25 July 1995)

Surfaces eroded by ion sputtering are sometimes observed to develop morphologies which are either ripple (periodic) or rough (nonperiodic). We introduce a discrete stochastic model that allows us to interpret these experimental observations within a unified framework. We find that a periodic ripple morphology characterizes the initial stages of the evolution, whereas the surface displays self-affine scaling in the later time regime. Further, we argue that the stochastic continuum equation describing the surface height is a noisy version of the Kuramoto-Sivashinsky equation.

$$W \approx t^\beta$$

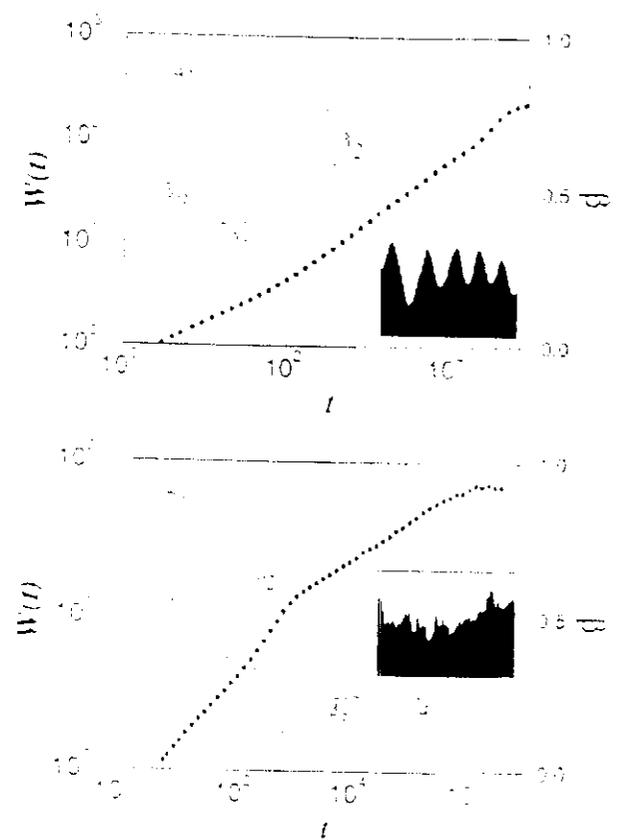

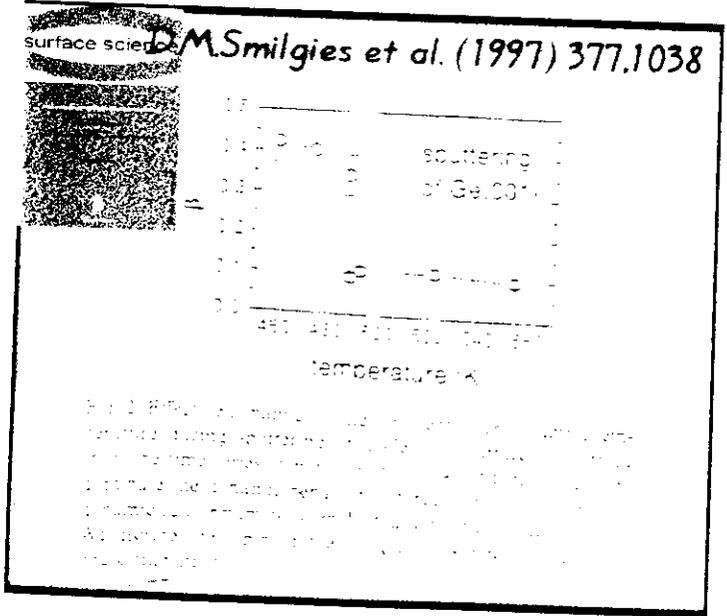

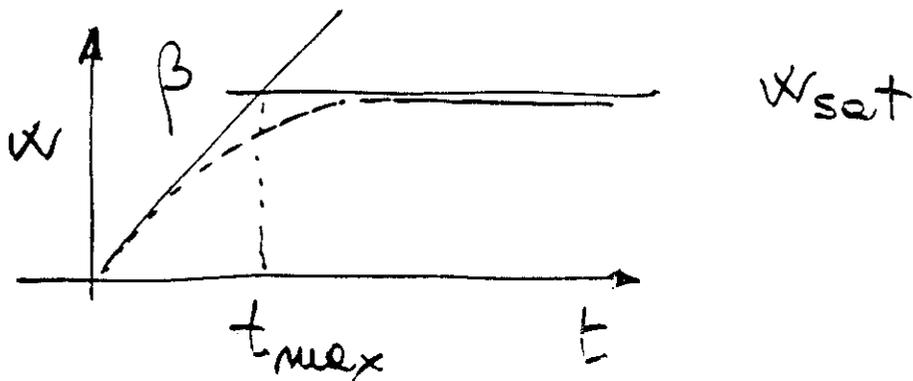

FIG. 2. Time evolution of the surface width for the case $\beta = 0.5$ and $\beta = 0.9$. The solid line is the cumulative slope of the width, showing the value of the growth exponent β in each regime. The inset shows the ripple structure of the interface at $t = 10^3$. The saturation observed at $t = 10^4$ is due to the discreteness of the lattice; the erosion rate drops down when the mean slopes of the interface are bigger than $\pi/20$. This effect can be eliminated by using a bigger 20×20 interface width as a function of time for the full model, showing the emergence of the saturation for $\beta = 0.48$. As in (a), the solid line is the cumulative slope. The inset shows a portion of the rough morphology of the late regime, where the self-affine scaling holds (at $t = 10^3$). The arrows indicate the times at which the structure changes displayed in Fig. 3.

Scaling laws -

$$W \sim t^\beta \quad \beta \text{ growth exponent}$$

$$W_{set} \sim L^\alpha \quad t \gg t_x$$

α roughness exponent

t_x depends on the system size

$$t_x \sim L^2$$

α β and γ are not independent

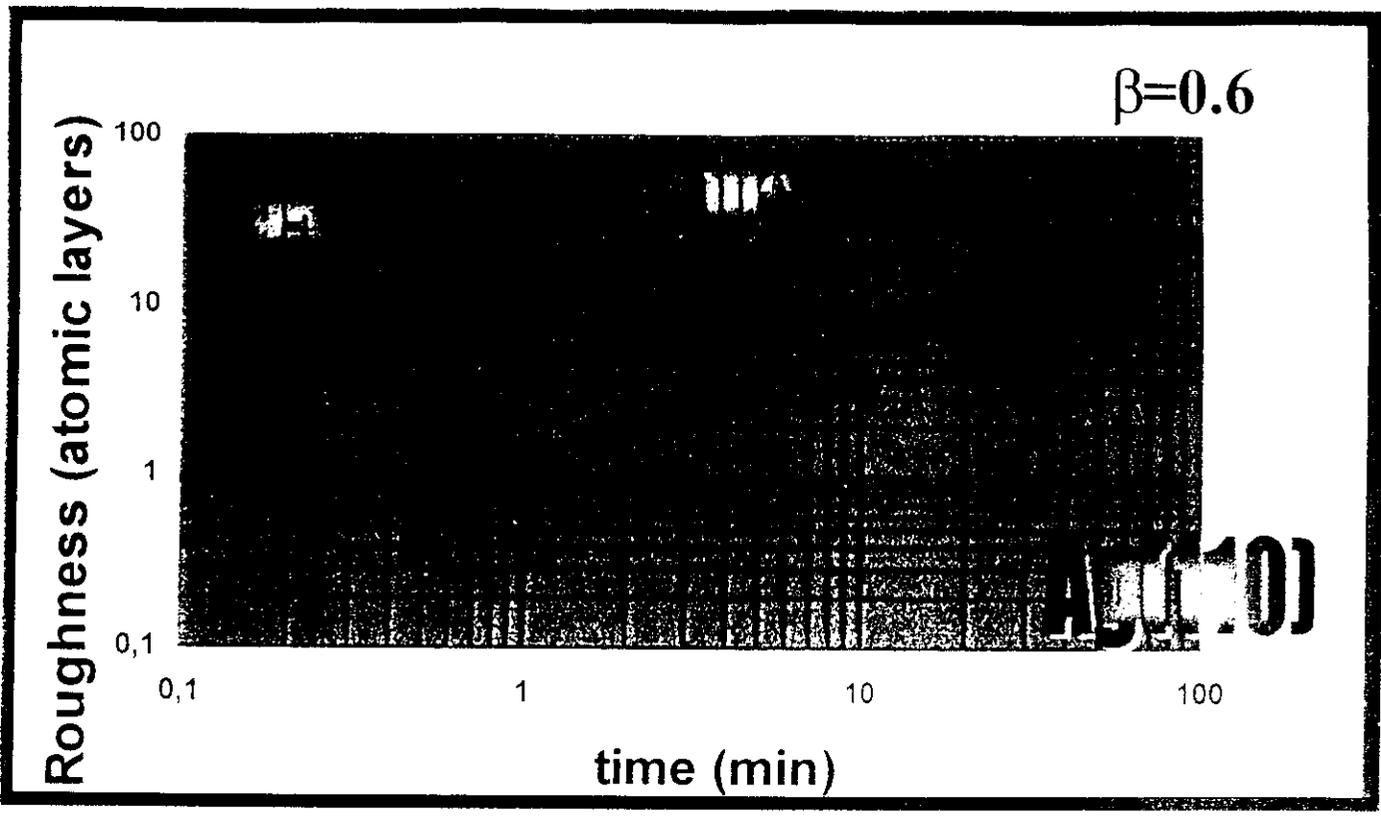

$$\gamma = \frac{\alpha}{\beta}$$

Family - Vicsek scaling relation -

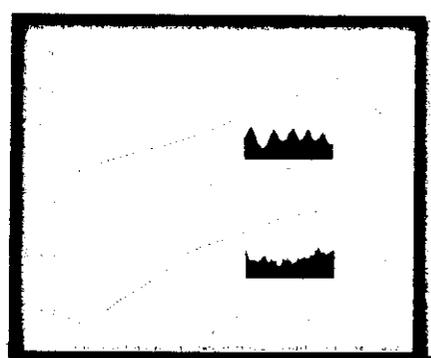

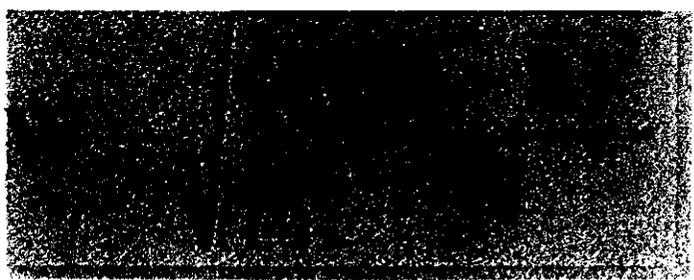

$$w\left(\frac{L}{L_c}\right) \sim L_c^{-\alpha} \left(\frac{L}{L_c}\right)^{\beta}$$

$$\frac{w(L_c)}{w_{\text{sat}}(L_c)} \sim \left(\frac{L}{L_c}\right)^{\beta}$$

 h surface mean height

Scaling law

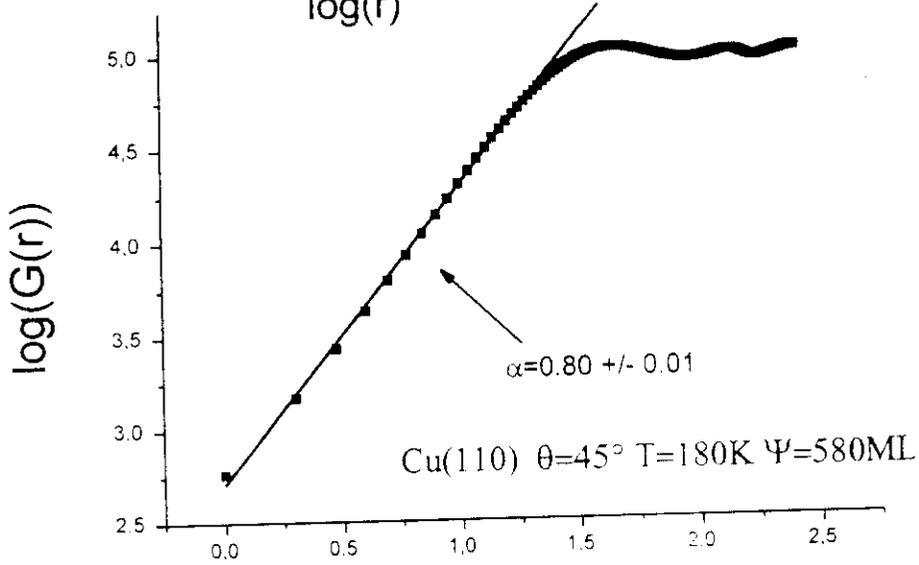

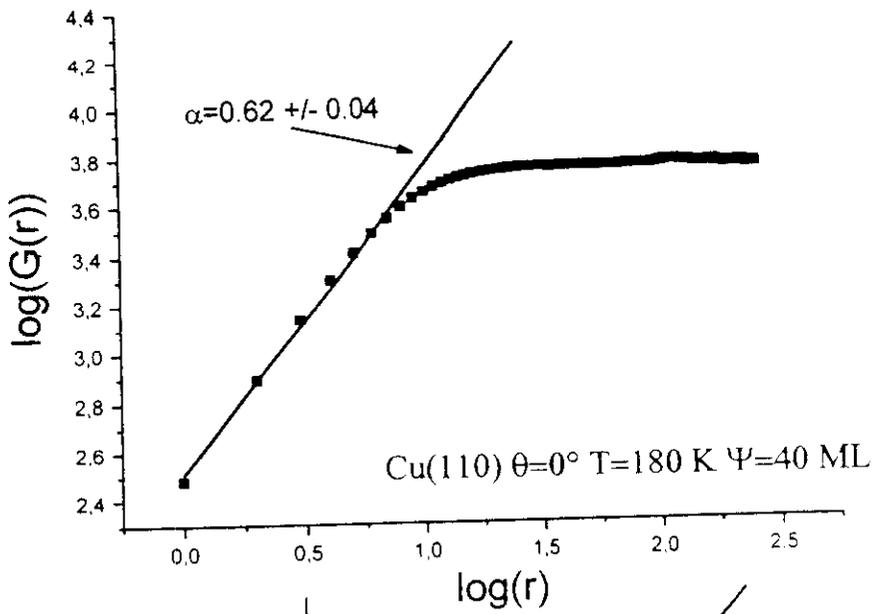

Family, Physica A 168 (1990) 561

Time evolution of roughness and ripple wavelength

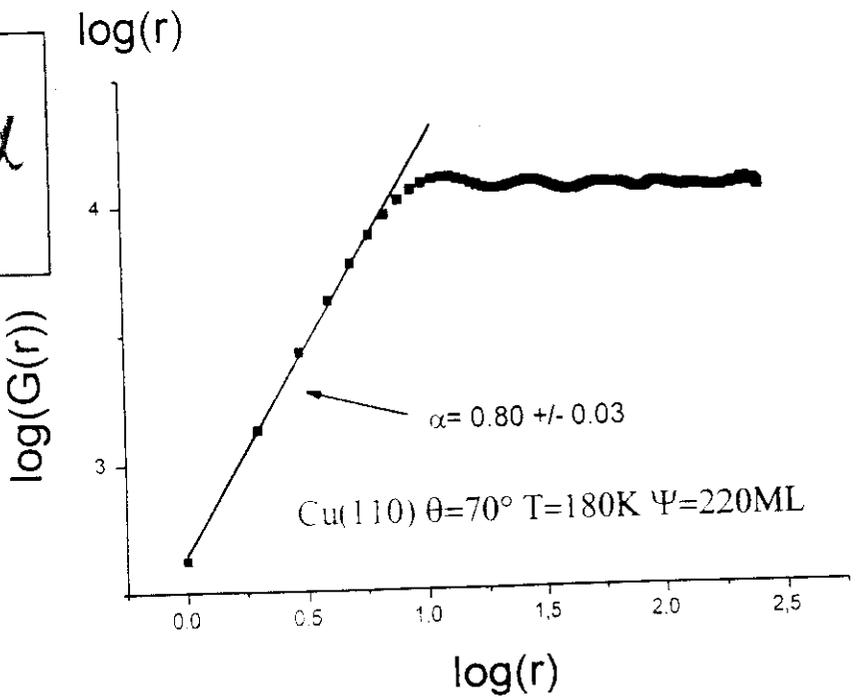

$T = 180 \text{ K}, \theta = 45^\circ, \delta = 0^\circ, \Phi = 0.09 \text{ ML/sec}$

Two scaling laws: $\lambda \propto t^{0.25}$, $W \propto t^{0.43}$

$$W \propto L^\alpha$$

The wavelength grows as $\lambda \propto t^{0.25}$, with the same scaling law observed in MBE growth when a Schwoebel barrier is present cfr. Fe/Fe(001), Cu/Cu(001)

in sputtering process the presence of a Schwoebel barrier is important to determine the final morphology

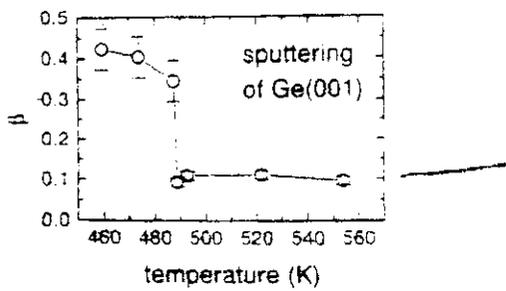

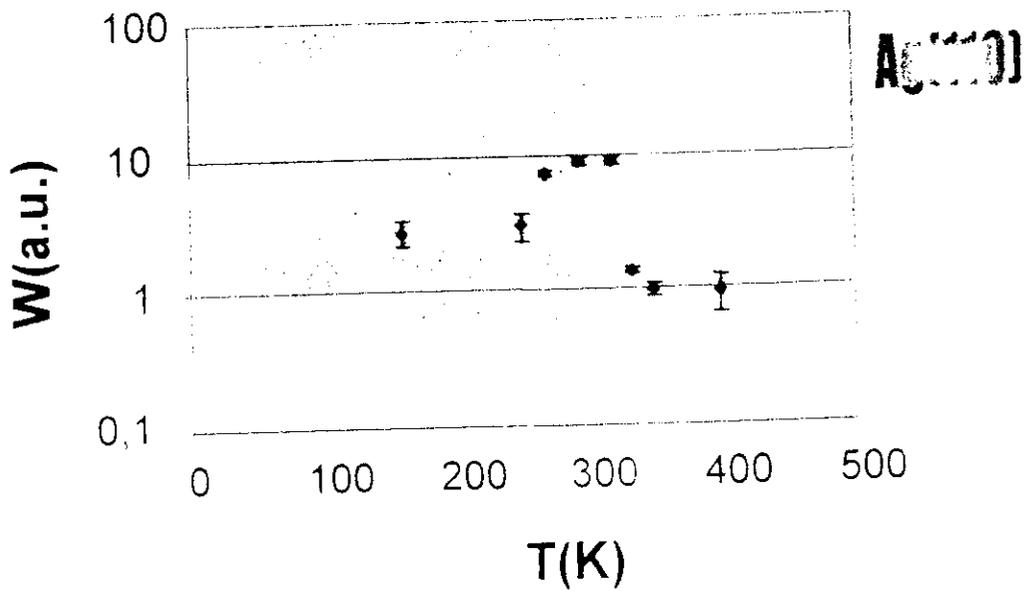

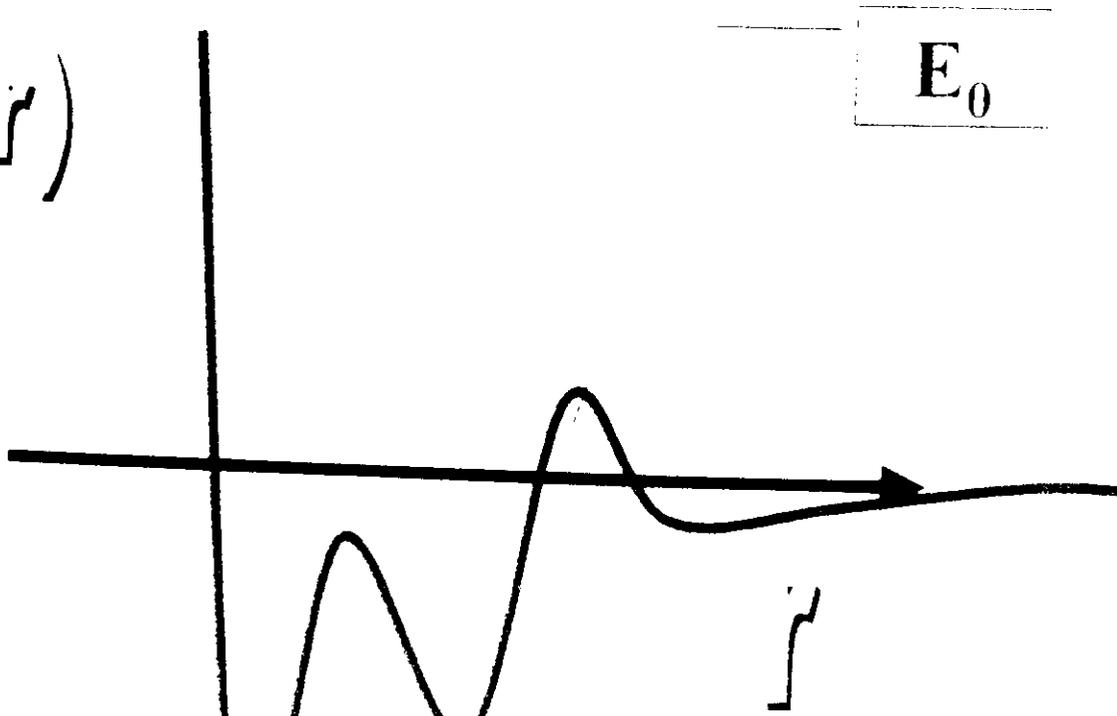

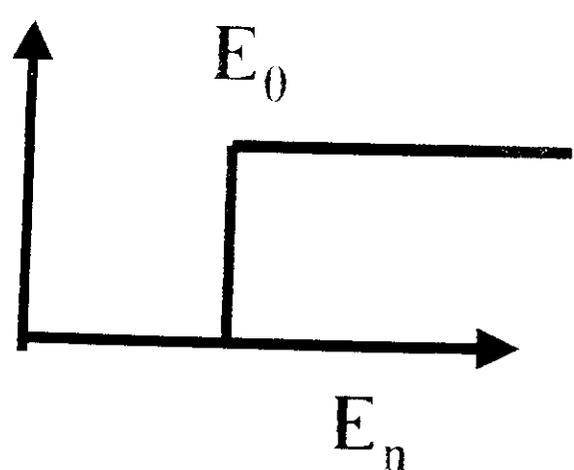

Fig. 2. Effective dynamic scaling exponent β versus sample temperature during sputtering of a Ge(001) surface, as derived from the time series in Fig. 1. For $\beta \approx 0.4$ random fluctuations dominate the dynamic behavior, whereas for $\beta = 0.1$ there is a dynamic equilibrium between fluctuations and surface diffusion. We ascribe the jump of the β value at 488 K to a dynamic phase transition.
