INTRODUCTION

Objectives:

- Achievement of 3D resist microstructures in only one shot
- Modulation of the x-ray dose by using a grey tone mask

Simulation of illumination effect

By computer simulation, we obtain this shape for the developed resist exposed by the x-rays passing through the described mask

National Nanotechnology Laboratories

FIGURE 13-1 Illustration of excitation-light path in wide-field epifluorescence or confocal (A) microscopy and two-photon excitation microscopy (B). In (A), the illumination occurs throughout the field of view, whereas in two-photon excitation fluorescence microscopy, it is limited to a spot at the focal plane of the infrared laser beam.

Two photon lithography

FIGURE 3-8 Spatial extension of the fluorescence emission from a solution containing fluorescent molecules under one- and two-photon excitation. In the case of TEP, the excitation phenomenon, small spots in the lower part of the cuvette, takes place only within a diffraction-limited volume. This volume can be roughly quantified using the resolution parameters of the system. In the case of conventional or one-photon excitation, the double-cone geometry (the upper bright area in the cuvette) is evident. The main implications of this behavior are an inherent confocal effect and consequent optical sectioning property, and photobleaching and phototoxicity confined to a sub-femtoliter volume. (Picture courtesy of John Girkin from Biorad web homepage.)

$$\text{2Photon absorbtion} \propto I^2 \propto \frac{1}{r^4}$$

Fig. 2. (a) The absorption spectrum of resin, a mixture of urethane acrylate monomer/oligomer and two kinds of benzoyl initiators, for short, BDME and HCAP, (the inset). The emission spectrum of a fluorescence dye used for 3-D microdiagnosis (see Section VIII) is also shown. (b) Typical reaction of radical production via an α -cleavage process. Radicals are produced in HCAP entirely by and in BDME mostly by this mechanism. Note negligible single photon absorption at the working wavelength of 780 nm.

Fig. 3. Schematic two-photon laser precision microfabrication system. The use of femtosecond laser and tightly focusing light by a high NA lens (1.4, oil immersion used here) is critical to launch the TPA polymerization process. The output stability of laser pulse energy and the accuracy of focal spot/sample scanning are the most important factors that guarantee a high precision fabrication. The imaging system using an CCD camera is useful both for optical adjustment and for *in situ* fabrication monitoring. PBS: polarization beam splitter, OL: objective lens.

actual reactions involved in practical photopolymerization systems were more complicated, however, the principle of electron excitation, radical generation, and chain photopolymerization is as described above.

III. LASER PRECISION MICROFABRICATION SYSTEM

Typical cross sections for one- and two-photon processes are

Mode locked Ti:sapphire laser

- wavelength: 790 nm
- repetition rate: 76MHz
- pulse width: 120 fs
- peak power: 50mW

S. Maruo et al., Optics Lett. 22, 132 (1997)

3D manipulation et al: Optical Tweezers, Two Photon lithography, two photon microscopy

L'uso combinato di forbici e pinze laser consente di effettuare delicate manipolazioni a livello subcellulare. Nella procedura illustrata, che dovrebbe essere realizzabile entro una decina d'anni, due fasci che fungono da pinze (*in rosa*) trattengono strettamente la cellula. Un fascio forbice (*in blu chiaro*) penetra nella cellula per eliminare un gene difettoso (*in rosso*). Un secondo fascio forbice (*in blu scuro*) crea nella membrana cellulare un foro attraverso il quale potrà entrare una sequenza genica appropriata (*punti neri*). Si potranno poi ottenere cloni della cellula modificata che saranno trapiantati a scopo terapeutico.

TASC - INFN

Optical tweezers - background

How do Optical Tweezers work ?

Two regimes of operation:

- ▷ Rayleigh regime (size of particle $\ll \lambda$)
- ▷ Mie regime (size of particle $> \lambda$)

Ashkin, A.; Dziedzic, J. M.; Bjorkholm, J. E.; and Chu, S., "Observation of a Single-Beam Gradient Force Optical Trap for Dielectrical Particles", Optics Letters 11, pp 288-290 (1986) - ray optics model

Rayleigh regime

$$F_s = \frac{8}{3} \pi (k^4 d^4) d^2 \frac{\sqrt{\epsilon_0}}{c} \left(\frac{\epsilon - \epsilon_0}{\epsilon + 2\epsilon_0} \right)^2 S$$

$$\mathbf{F}_g = 2\pi d^3 \frac{\sqrt{\epsilon_0}}{c} \left(\frac{\epsilon - \epsilon_0}{\epsilon + 2\epsilon_0} \right) \nabla |\mathbf{S}|$$

S - Poynting vector
 d - size of particle
 ϵ - dielectric constant of particle
 ϵ_0 - dielectric constant of medium
 k- wavenumber

Two main forces:

- ▷ Scattering force, \mathbf{F}_s
- ▷ Gradient force, \mathbf{F}_g

$$\mathbf{F} = \mathbf{F}_g + \mathbf{F}_s$$

Optical manipulation of liposomes as microreactors

Figure 2: Schematic representation of the procedure for the trapping and fusion of two liposomes, containing different chemicals. a) Two liposomes, one containing reagent A and the other one containing reagent B, are identified in the sample. b) The two liposomes are trapped in separate optical tweezers and translated such that their membranes come into contact. c) Fusion is initiated by a pulsed UV laser, which disrupts the membranes of both liposomes at the contact point. d) The membranes repair spontaneously by forming one larger liposome in which the reagents A and B mix.

Figure 3: Fusion of two liposomes. The images are recorded by video microscopy. The fusion was initiated by the UV laser at the time when the first image was recorded. The next two images capture the progression of the fusion process at 132ms and 264ms, respectively. The last image, recorded at 528ms, shows one single large liposome formed as a result of the fusion.

Figure 6: Fusion of two liposomes, one containing fluo-3 dye and the other one containing calcium ions. The bright field video microscopy images and the fluorescence images recorded simultaneously before and after the fusion was initiated (upper and lower images, respectively). After the fusion the fluorescence increases as a consequence of the reaction in which fluo-3 chelates the calcium ions.
