& PALS users

Focusing the laser beam on a (slab) target
Repetition rate of PALS accelerated 500 ×,
the real repetition rate ~30 minutes

Utilisation of pulsed kJ-class lasers in science & technology:

Experiments with the plasma produced on
solid-state and gas-puff targets by
focused high power laser beams

Study of interaction of intense laser radiation
with matter

PALS is the Joint Research Laboratory between
IP and IPP of ASCR

Key facilities:

3-TW iodine laser system PALS

100-MW Zn soft x-ray laser PALS-X

25-GW hybrid laser SOFIA

NATIONAL IGNITION FACILITY (NIF)

The National Ignition Facility

The NIF building complex was completed in September 2001. Spanning the length of two football fields, the facility will house 192 laser beams in two bays in precision-aligned and environmentally controlled conditions. The aerial photograph of the NIF facility has been combined with a computer-generated model revealing one bay of the laser system. NIF is scheduled to deliver its first laser light to the target chamber in 2003 and will be completed with all 192 laser beams operational in 2008. You are invited to follow the progress of NIF on our web site <http://www.llnl.gov/nif>.

1 The NIF laser contains more than 3000 pieces of amplifier glass. They are cleaned and assembled into modules before automated guided vehicles install them into the laser system.

2 The cable plant delivers electrical power to the flashlamps in the amplifier system.

3 Beam tubes transport laser light to the target chamber.

4 Slices of giant crystals convert the infrared lasers to ultraviolet light before the beams enter the target chamber.

6 The NIF Control Room controls all aspects of the laser system and target experiments.

5 At the center of the 10-meter-diameter target chamber, the 192 ultraviolet laser beams converge on the target.

7 A 360-degree panorama of the Class 100 clean room facility in the Optics Assembly Building.

NIF TARGET CHAMBER

***PALS** history and characteristics*

PALS history and characteristics

Place of birth : MPQ Garching, Germany
Transfer to Prague : 1997-1998
Reassembling of the system finished in autumn 1999
Operational tests : November 1999 – May 2000
Launching : 7 June 2000
Users experiments since September 2000

Basic characteristics:

Pulsed single beam iodine photodissociation laser
Fundamental wavelength: $1\omega = 1315$ nm (infrared)
Red, blue and UV harmonic beams
Pulse duration: ~ 0.4 ns
Output beam diameter: 290 mm
Output energy at 1ω : 10 J - 1 kJ

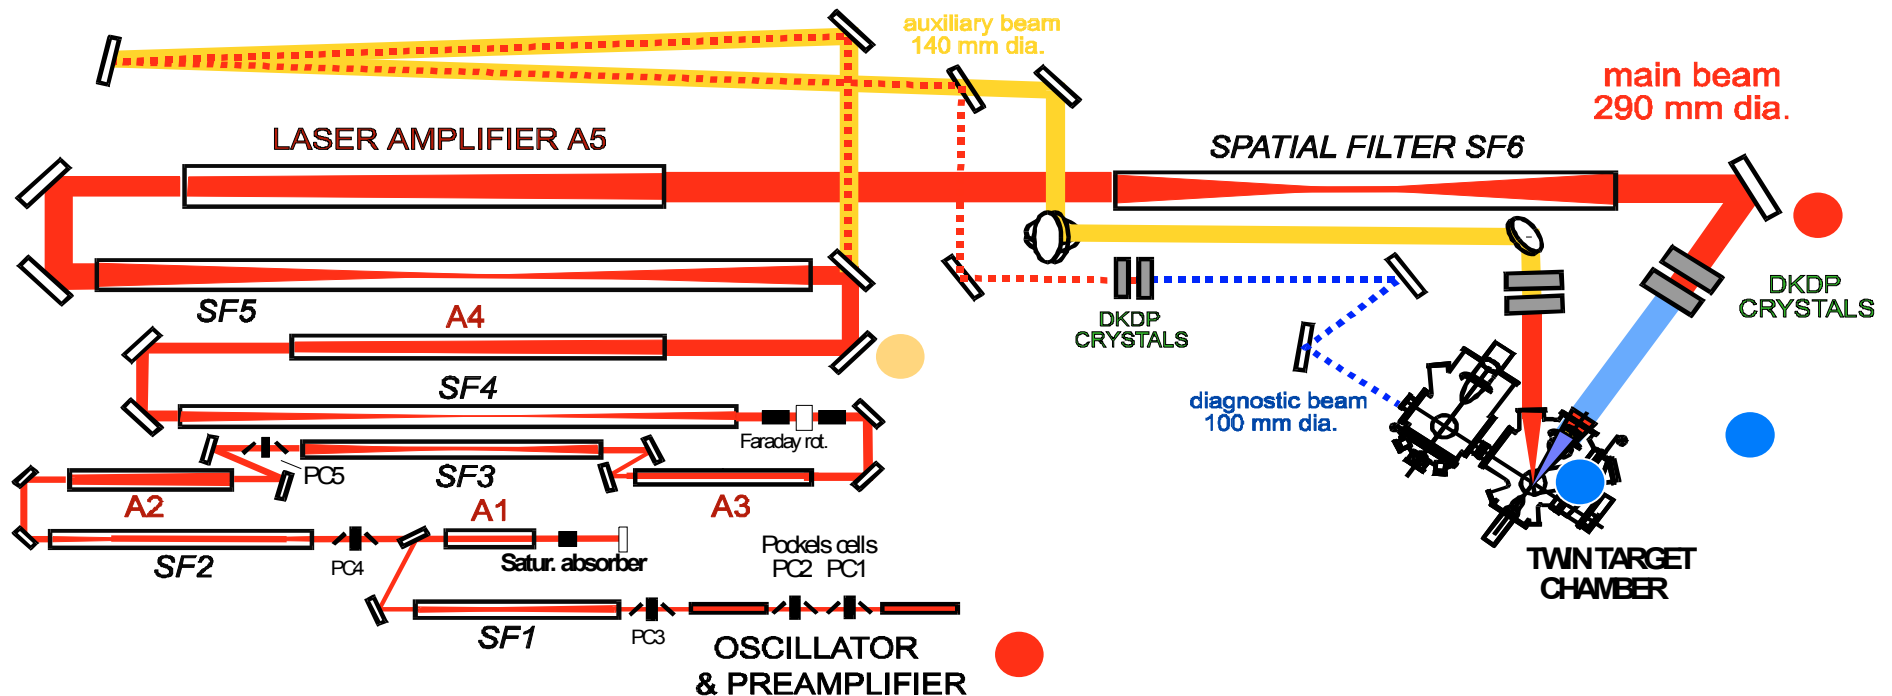

PALS unique features

- iodine gas laser, working wavelength 1315 nm
- laser of the highest energy in Europe
in a single beam configuration

6 gas laser amplifiers + 6 spatial filters

Main, auxiliary and diagnostic different-color beam lines

Schematic of the laser beam lines

***PALS** target facilities*

PALS target facilities

Unique twin target chamber

Achievable power density at the target $> 10^{16}$ W/cm²

Several different-colour laser beam lines

Both point and linear focusing optics available

Advanced equipment for ion and x-ray diagnostics

Arrangement for x-ray laser experiments

Equipment for shock wave studies

PALS main beamline output end

to the
target

PALS target chamber

**MAIN BEAM
ENTRANCE WINDOW**

**ENTRANCE WINDOW in
the cylindrical chamber**

View in the target chamber

There are thousands of things one can do with a nanosecond high power laser:

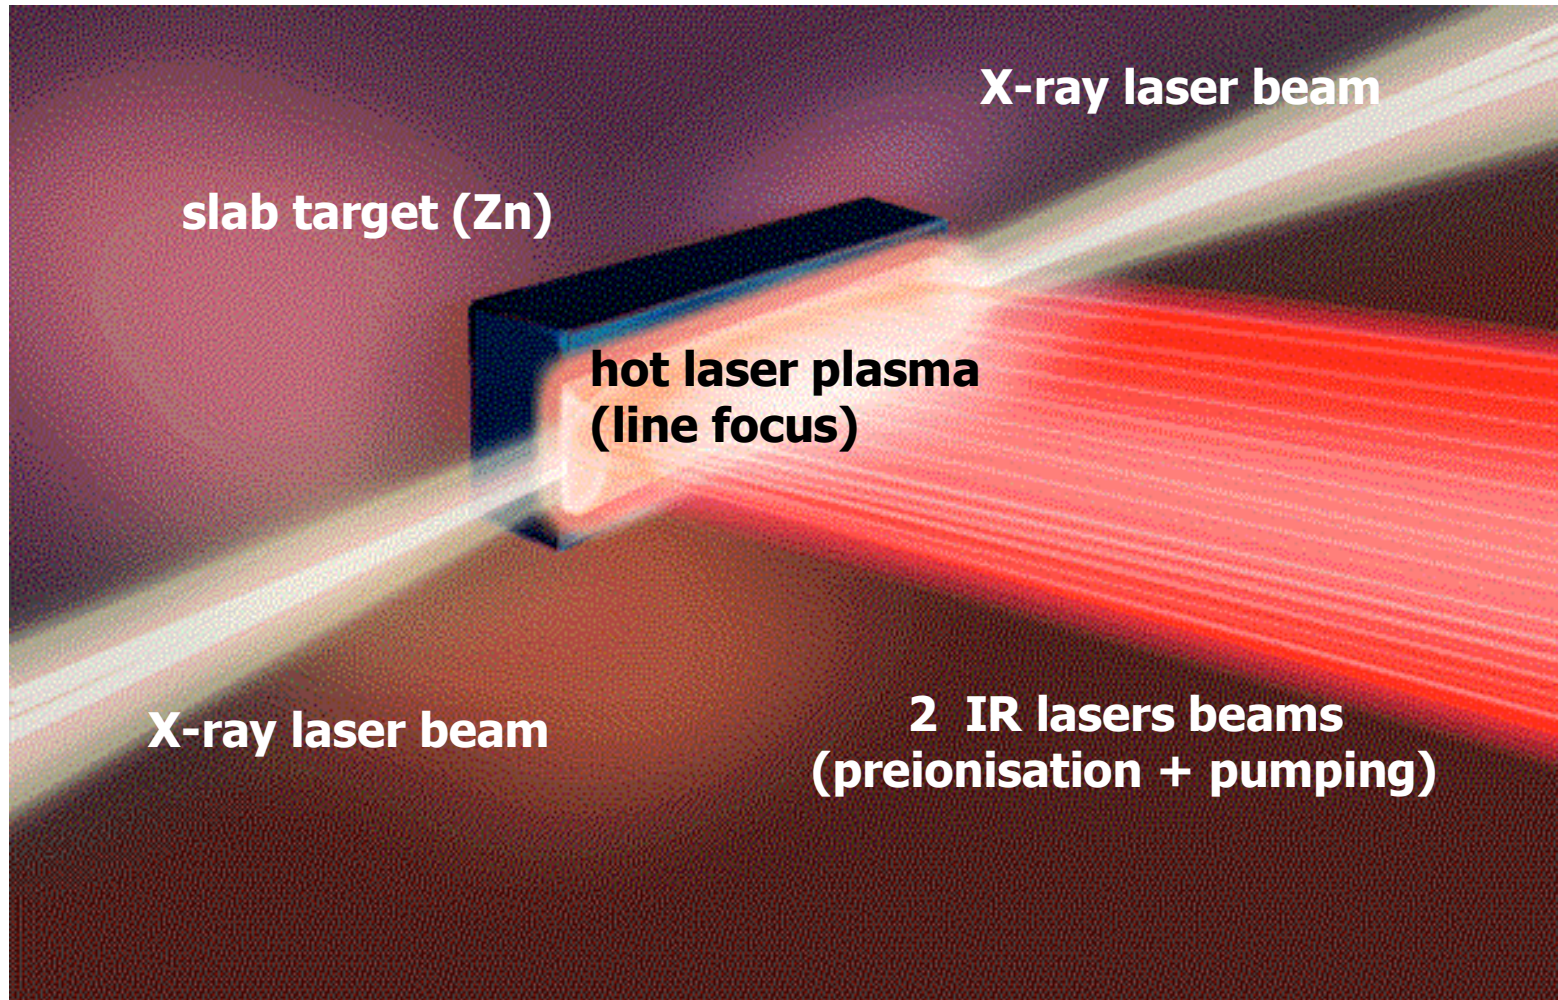

- XUV spectrometry
- fusion related experiments
- generation of shock waves
- incoherent X-ray sources
- ion sources
- impact studies
- etc

BUT the new science is to be sought either in the domain of *short wavelength* or *ultra short high intensity pulse*

How to get into the domain of short wavelength?
Operate a sufficiently intense X-ray laser

PALS

Generic scheme of an x-ray laser experiment

Plasma-based QSS XUV Zn laser

working wavelength 21.2 nm

double-pass, saturated

Unique features:

- record brightness
- suitable for routine science & technology applications
- maximum intensity at the shortest wavelength

Saturated double-pass XUV laser on Ne-like zinc at 21.22 nm (58.53 eV)

Launched June 2001

Optimised November 2002

Experimental arrangement

main beam 600 J
auxiliary beam 1,5 J

Development of the PALS-X XUV laser

div. 3.5x5.5 mrad Δt
= 10 ns
(2001)

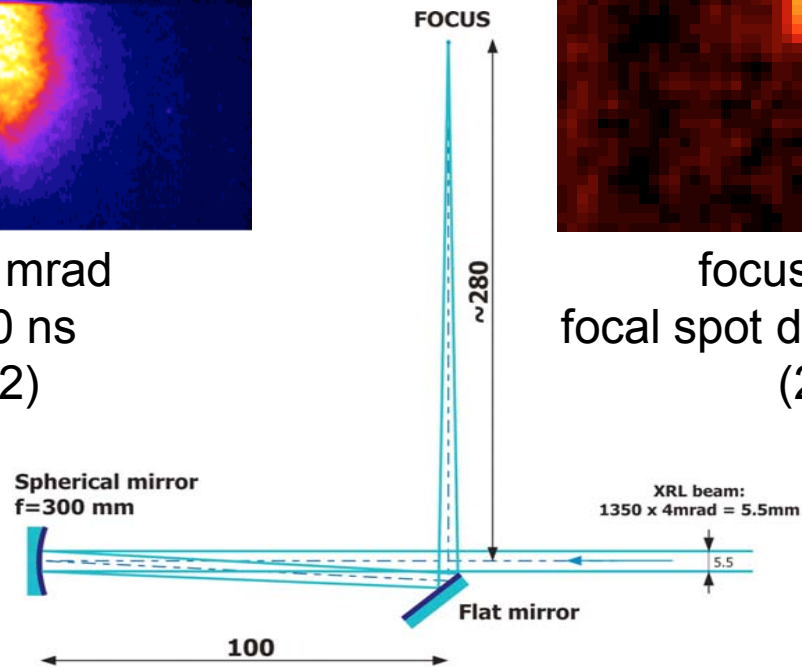

div. 1x4 mrad
 Δt = 50 ns
(2002)

1x1 mm
focused beam
focal spot diameter $\sim 50 \mu\text{m}$
(2004)

Pulse duration 80 - 100 ps
Beam energy 4 - 10 mJ
Pulsed power 40 - 150 MW

Brightness
 $> 3 \cdot 10^{27} \text{ phot. s}^{-1} \text{ mm}^{-2} \text{ mrad}^{-2}$

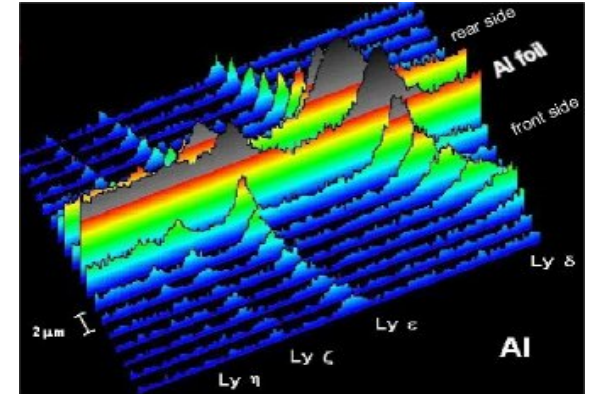

Focal intensity $\sim 4 \times 10^{10} \text{ Wcm}^{-2}$

PALS

A users facility providing transnational access

25 users projects completed since IX 2000

12 new projects are ahead

Laser soft x-ray sources

Time- and space-resolved x-ray spectroscopy

Contact XUV microscopy

XUV ablations studies

XUV interferometry of surfaces

Neon-like zinc x-ray laser (21.2 nm)

the brightest XUV laboratory source ever built in

PALS

Crater formation studies

Ion implantation studies

Laser ion sources

Multiframe laser interferometry

Shock wave studies

PALS co-laborators

57 different users made at PALS 107 visits of an average duration of 12 days and spent there till November 2003

1295 days

31

Research programmes at the facilities

PALS terawatt laser system

Laser-matter interaction at focused power densities $10^{14} - 10^{16} \text{ W/cm}^2$

- laser-plasma dynamics
- ablation pressure studies (laser imprint smoothing)
- generation of shock waves (EOS studies at high pressures)

Development and applications of

- soft x-ray sources (XUV lithography, photo-etching, microscopy)
- laser ion sources (ion injection and implantation)

QSS plasma-based XUV lasers

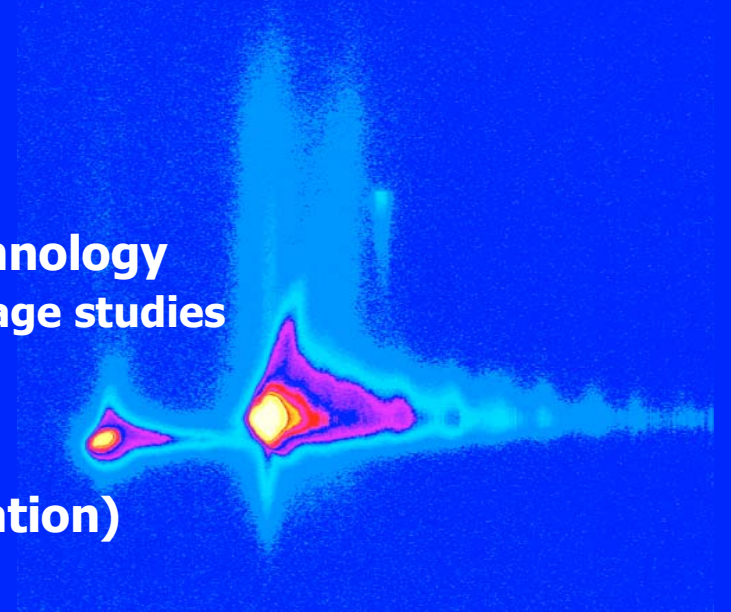

Testing new laser schemes

Application of XUV lasers in science and technology

- interferometry, laser ablation & radiation damage studies

SOFIA

Generation of fs pulses (OPCPA implementation)

Applications of the zinc soft x-ray laser

Nanometric x-ray interferometry of surfaces

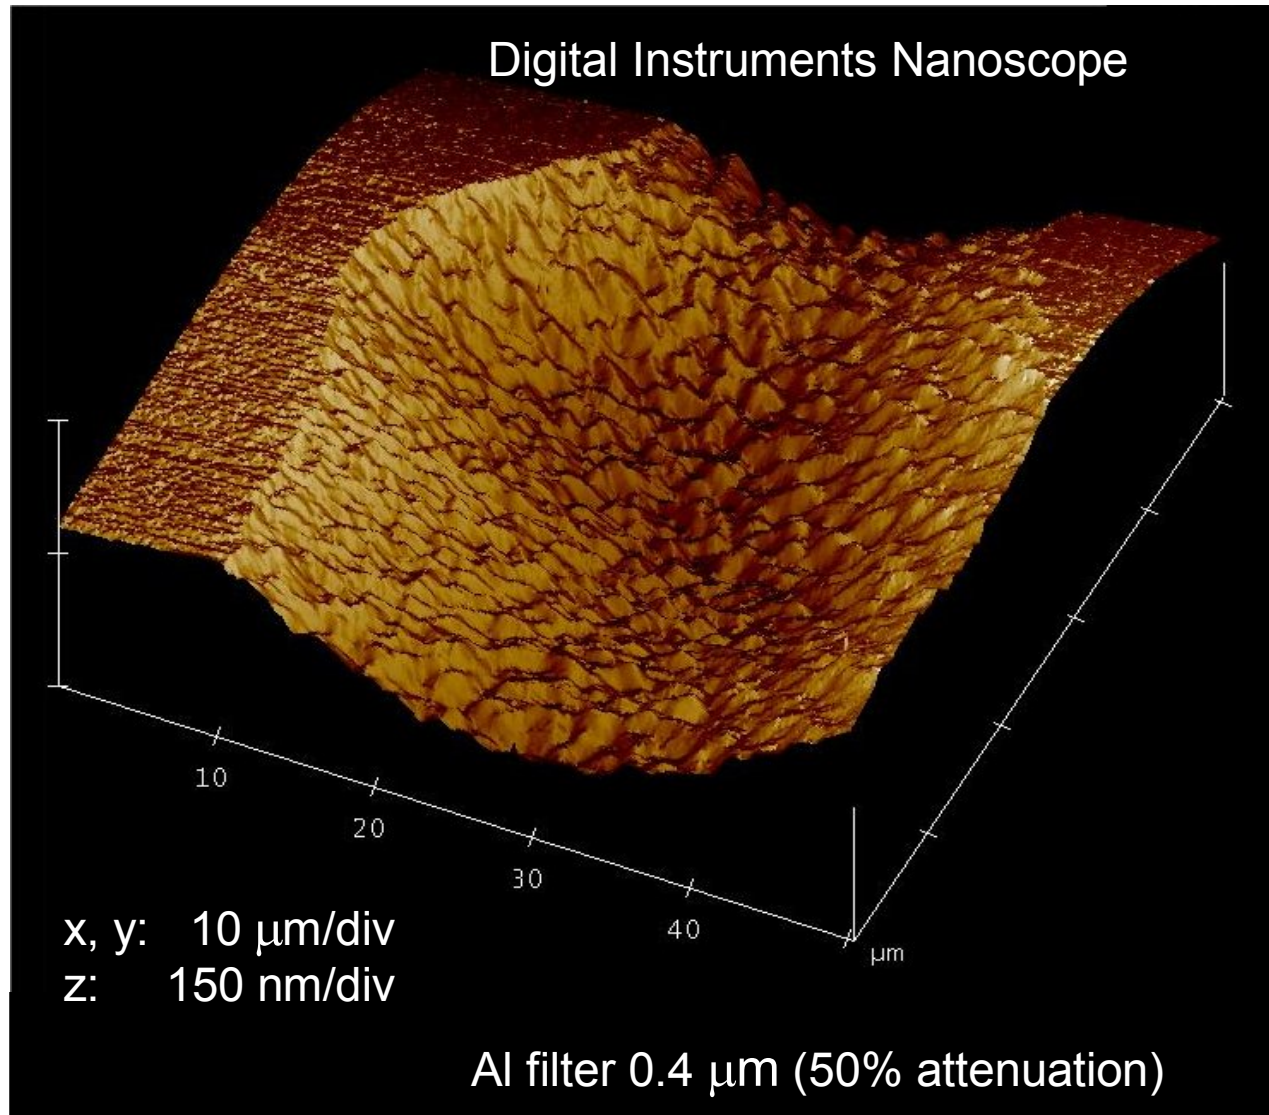

Fresnel grazing-incidence interferometer
(Zn laser, 21.2 nm)

Nanometric soft x-ray interferometry used for the first time for studies of pre-breakdown processes on Nb-coated electrode surfaces in strong electric fields (the main limiting factor at construction of charged particle accelerators).

Co-operation: LSAI (CNRS Orsay), IOTA (Univ. Paris Sud), CEA-SEA (Saclay)

XUV ablation studies with the PALS XUV laser (April 2004)

AFM image of the crater ablated in PMMA by a focused beam of the PALS XUV Ne-like Zn laser (21.2 nm).

To our knowledge, this was the first observation of material ablation and plasma production with a laser operating in the XUV region ($\lambda < 30$ nm).

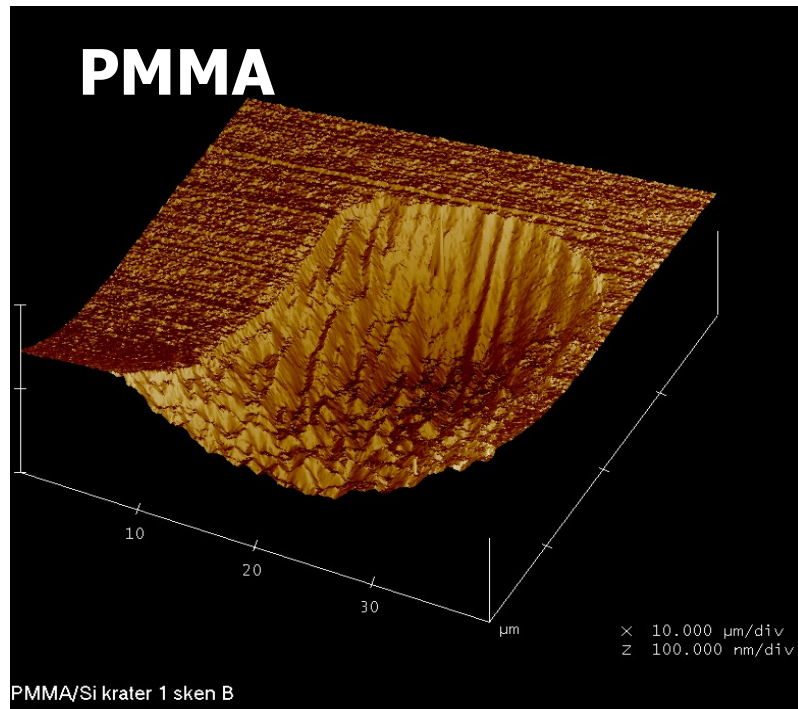

Pictures made in the new Nanoscopy Laboratory of IP AS CR in May 2004.

PALS XUV Zn laser, single exposure 200 μJ

AFM in the tapped mode.

Ablation of PMMA and polycrystalline Si by soft X-ray laser

Single XRL shot, 0.4 μm Al filter
focused energy $\sim 100 \mu\text{J}$

Sharp edges of the crater:
ablation is predominant process involved

Single XRL shot, no filter
focused energy $\sim 200 \mu\text{J}$

Melted structures at the crater edge:
ablation and melting involved
(irradiance below ablation threshold)

Studies of radiation stability of DNA

First ever DNA radiation stability tests in the soft x-ray spectral region.

Single (SSB) and Double Strand Breaks (DSB) observed at radiation doses of 10-100 kGy

Electrophoretical analysis of a dissolved sample

Number of breaks per plasmid

Soft X-ray Contact Microscopy (SXCM) of living micro-organisms

PALS 1ω & 3ω
point focus

Au, Mo, PTFE
targets

$I > 10^{14} \text{ Wcm}^{-2}$

The first SXCM
application
for multicellular
organisms.

- XUV irradiation of samples + XUV spectroscopy
- developing of imprints on PMMA resists by etching
- AFM scanning of the etched relief

Irradiation cell for SXCM

OPTIMISATION OF LASER ION SOURCES

Generation of fast highly-stripped ions in solid-target plasmas

at various

- target material (Al, Cu, Mo, Ag, Ta, Au)
- beam energies (80-750 J)
- beam colours (1ω - 3ω)
- beam incidence angles
- focus position (FP) => focal spot size)

In parallel: Ion implantation experiments

- implanted ions: Cu, Ag, Ta
- samples: PET, PEEK, kapton, C, Al, Si, Ti
- Rutherford backscattering analysis of implanted samples

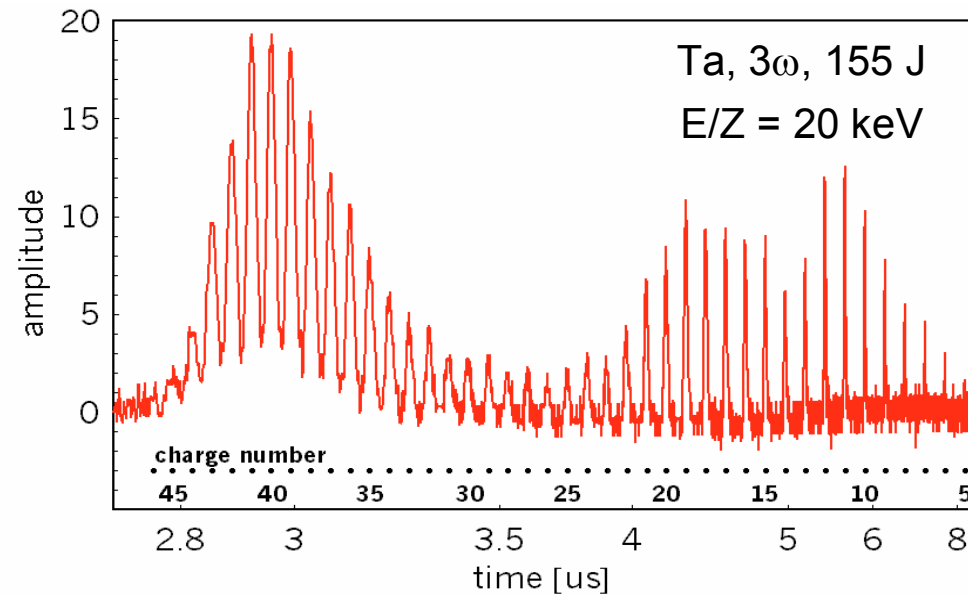

Participating Institutions:

IPPLM Warsaw, IPJ Swierk, INFN Catania, Universita di Messina, INP Rez, Light Ion Technologies Bad Abbach, PALS

Optimum focal point position for ion generation: FP = - (250-750) μm

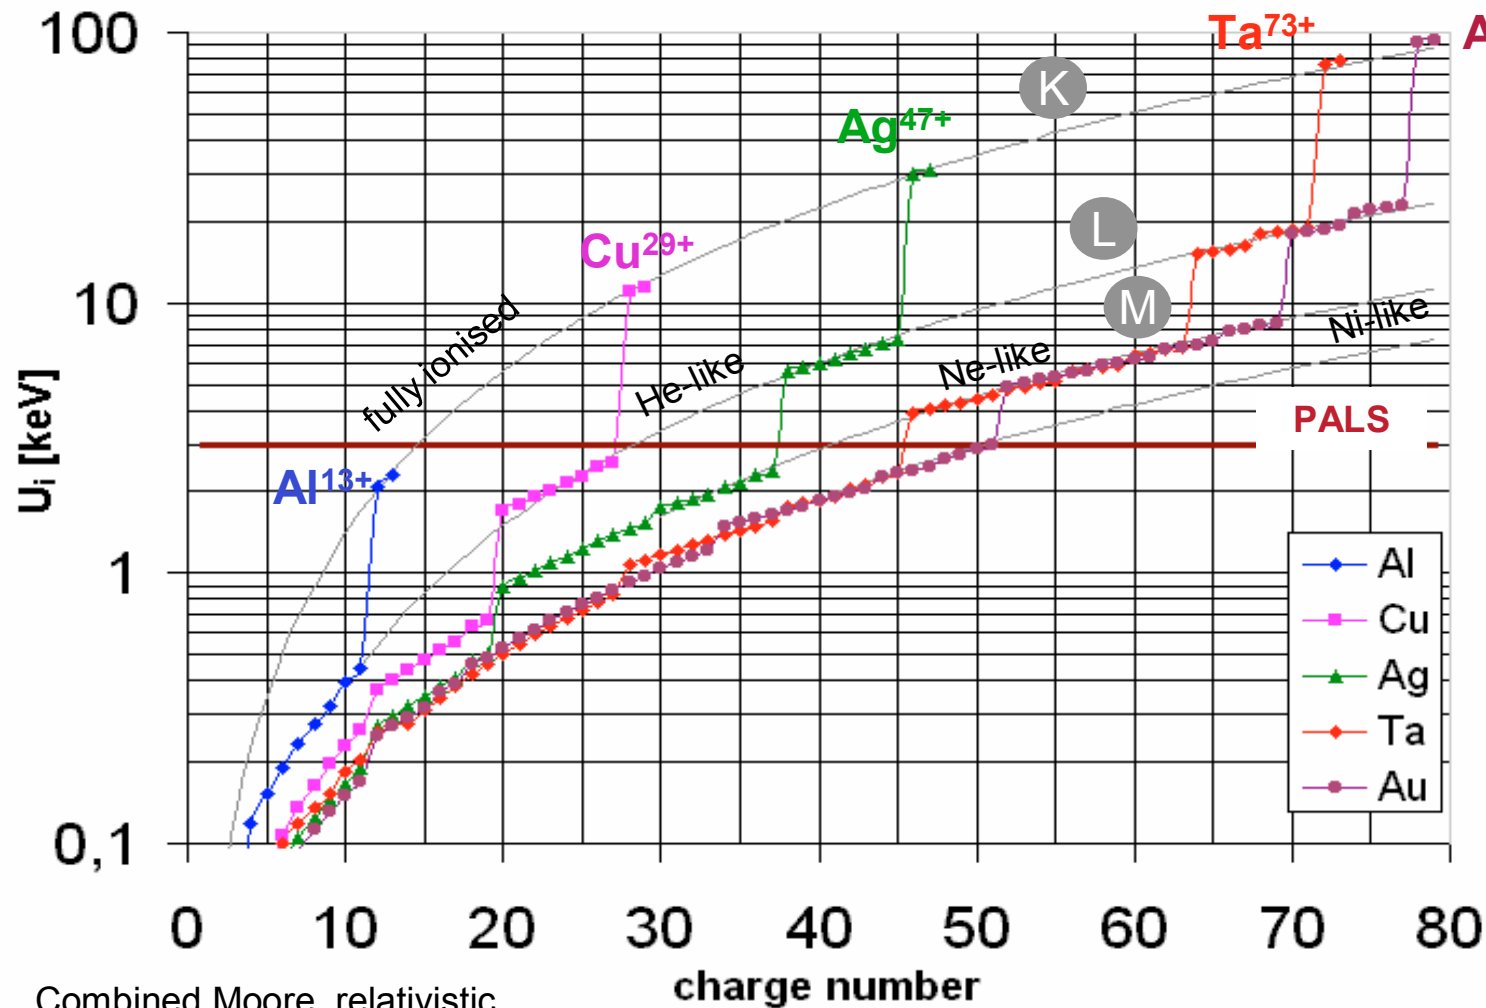

Ta ion charge spectra from EIA

Main results in general

- Several distinct groups of ions (by energy), evidently created by different mechanism and coming from different parts of the laser produced plasma.
- High energy abundant group of \sim MeV ions carries \sim 30 % of the energy in ions.
- Ultrahigh energy ions ($>$ 22 MeV), not seen in the EIA spectra, are witnessed by nuclear track detectors.
- Ion yield strongly depends on the laser beam focustion geometry - maximum at a slightly defocused beam (FP -0.2 mm).
- The maximum ion charge approaches $Z=50+$ for Ta or Au ions.
- High-energy ion fluxes, inhomogeneous (partially directional), ion current densities $>$ 1 mA/cm² (at a distance of 1 m)
- Efficient implantation of ions has been demonstrated, in up to depths of several hundred nm in metals, and several μ m in plastics.

Higher ionisation potentials of various elements

High energy jumps between e-shells
 Z^2 dependence within one shell
 3-5 keV needed for $Z > 50+$

Maximum ion charge observed at PALS:

Al 13+, Cu 27+
 Ag 36+, Ta 49+,
 (Au > 50+)

He-like ions : $A < 31$
 Ne-like ions: $A < 51$
 Ni-like ions : $A < 79$

Combined Moore, relativistic Hartree Slater and Hartree Fock calculations by J. Scofield, LLNL

=> High-Z ions originate in localised hot-spots, produced by non-linear processes (beam filamentation & self fousation). Just ions accelerated in local virtual cathodes to high energies escape recombination.

Maximum ion energies E_i/A at various laser power densities

Long-pulse lasers (Gitomer 1986)

ps-lasers (Clark 2000)

sub-ns, ps & fs lasers (Zhidkov 1999, Badziak 2003)

PERUN sub-ns laser (Laska 1996, 2002)

PALS sub-ns TW laser (2001-2003)

low-power ns-laser Catania (Laska 2002)

-  Ion energy scaling if non-linear effects are negligible
-  Increase in effective power density due to non-linear processes (e.g. laser beam self-focusing)

Laser-induced shock waves

- Studies of equations of states of C and Fe at Mbar pressures
- Smoothing effects of foam layers
- Phase transitions at very high pressures

Collaboration with Università degli studi di Milano-Bicocca, 2002-2004
(D. Batani et al.)

Stepped and layered targets
(Al-Al, Al-C, Al-Fe, CH-C-foam)

**Time-resolved (streak-camera)
imaging of the self-emissivity of the
target rear.**

- => Shock wave velocity
- => Shock pressure (Hugoniot data)

**Shock (ablation) pressures up to tens of
Mbar can be reached at PALS.**

PALS – Fusion related “Keep in Touch Activities”

Current issues:

Laser imprint smoothing in voluminous absorbers of low-density porous matter (foam targets)

In collaboration with IPPLM Warsaw (2002-2003)

Co-ordinators: J. Limpouch, T. Pisarczyk

Laser imprint smoothing in a plasma absorption layer produced by a laser prepulse

Current domestic experimental project

Co-ordinator: K. Mašek

Theoretical studies of electron and ion acceleration in crossed laser beams

Base for a new experimental project

Co-ordinator: V. Petržílka

IPP Laser Plasma Department

main operator of the PALS Research Centre

key facility: The Prague Asterix Laser System

Laser imprint smoothing

In a porous material
(foam):

In a prepulse-
produced plasma:

Thermal smoothing by a double laser pulse

K. Mašek, E. Krouský et al.

Pre-plasma produced by a defocused infrared beam
(focal spot diameter 0.3 mm)

Two hot spots generated by focused blue beams delayed by 0.5 ns.

Distance of the spots 0.2 mm.

Plasma expansion is studied by two X-ray pinhole CCD cameras.

X-ray backlighting provides shadowgrams of the dense plasma regions.

Laser beam lines in the double pulse arrangement

Targets and diagnostics

Second round of experiments just under way

A road towards a ultra intense multi petawatt pulse:
Futuristic vision of a full scale implementation of OPCPA on PALS
Calculations I. N. Ross, P. Matousek (RAL), B. Rus (Prague)

So far: a pilot laboratory SOFIA hybrid laser system: solid state tunable oscillator in combination with iodine amplifiers will drive a small scale OPCPA chain (two distinct upgrades)

SOFIA & OPCPA PILOT EXPERIMENT

SOFIA = Solid-state Oscillator
 Followed by Iodine Amplifiers

OPCPA = Optical Parametric
 Chirped Pulse Amplification

PALS FUTURE

Training site for domestic and foreign students

European users laboratory incorporated into the network of large European laser research centres

Co-operation with the USA, Japan, Russia and ...

Petawatt prospects: By shortening the pulse duration down to the femtosecond region (OPCPA technique) PALS has a potential to become one of the most powerful lasers in the world (OPCPA is a way to a multi petawatt)

When: ???, after a success of the SOFIA project and a good luck with a much more investment money
