The probability that a neutron interacts with a nucleus is expressed as a cross section σ , which has the dimension of an area

The unit of a cross section is taken as :

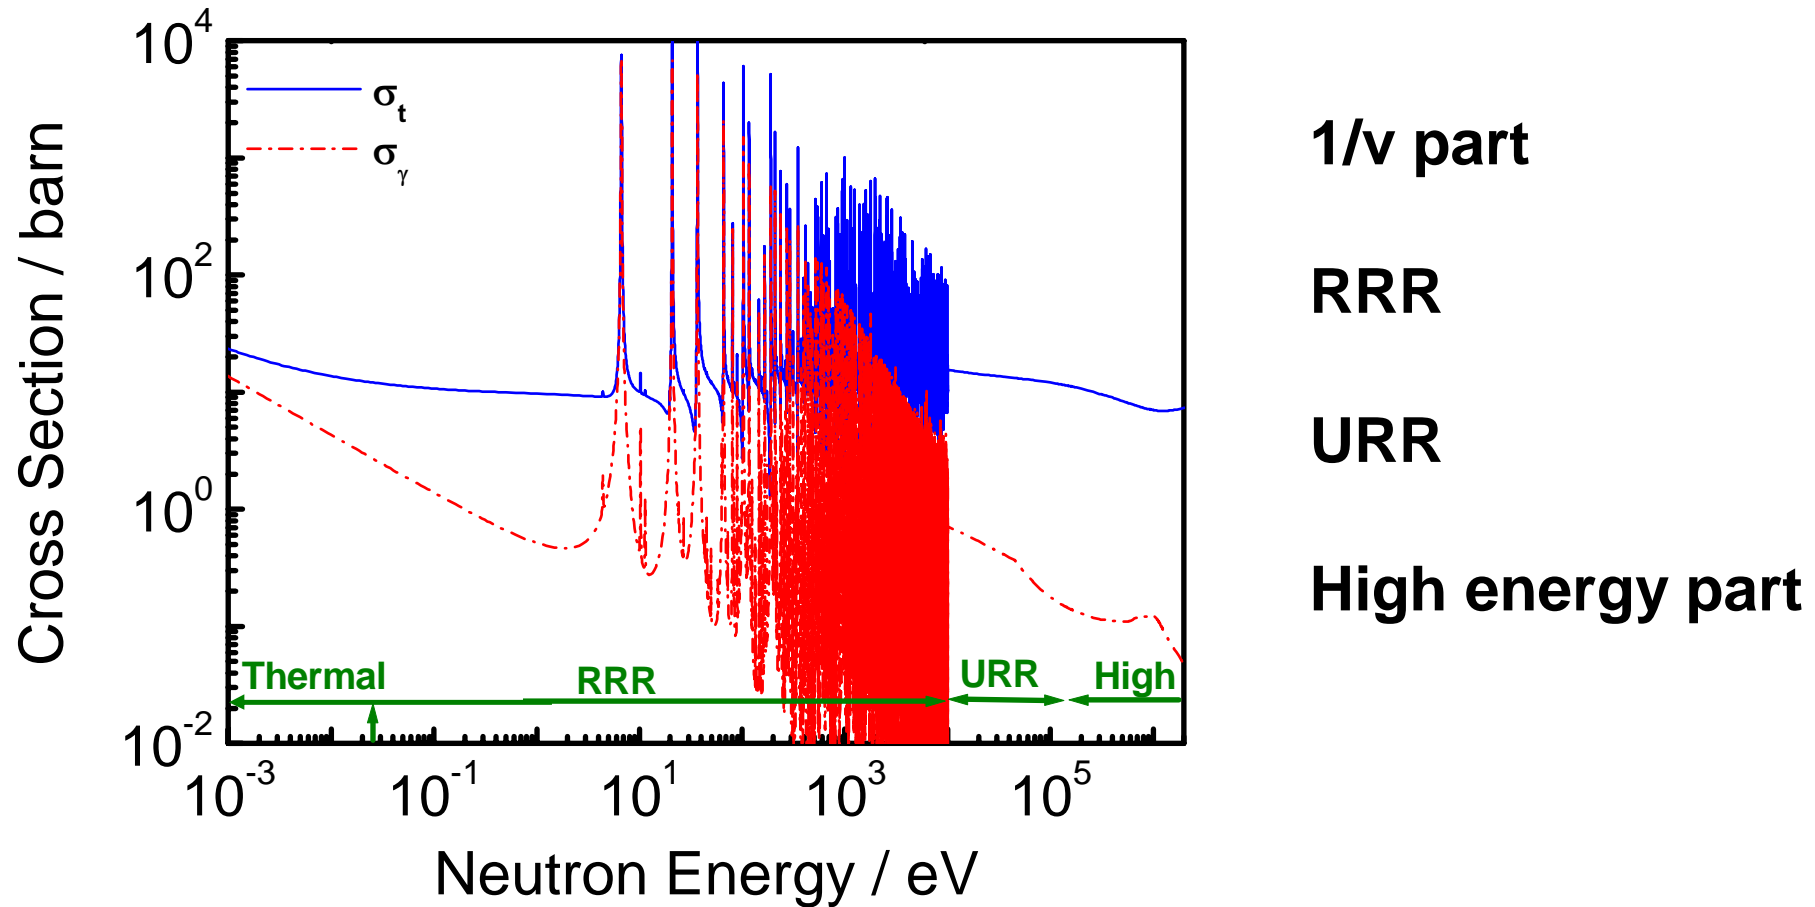

1 barn, 1 b = 10^{-24} cm²

To calculate reaction probabilities we express the target thickness in atoms per barn :

$$n = \frac{0.6022}{m_A} \rho t$$

- m_A : atomic mass
- ρ : density in g/cm³
- t : thickness in cm
- n : target thickness in at/b

Typical Cross Section shape (^{238}U)

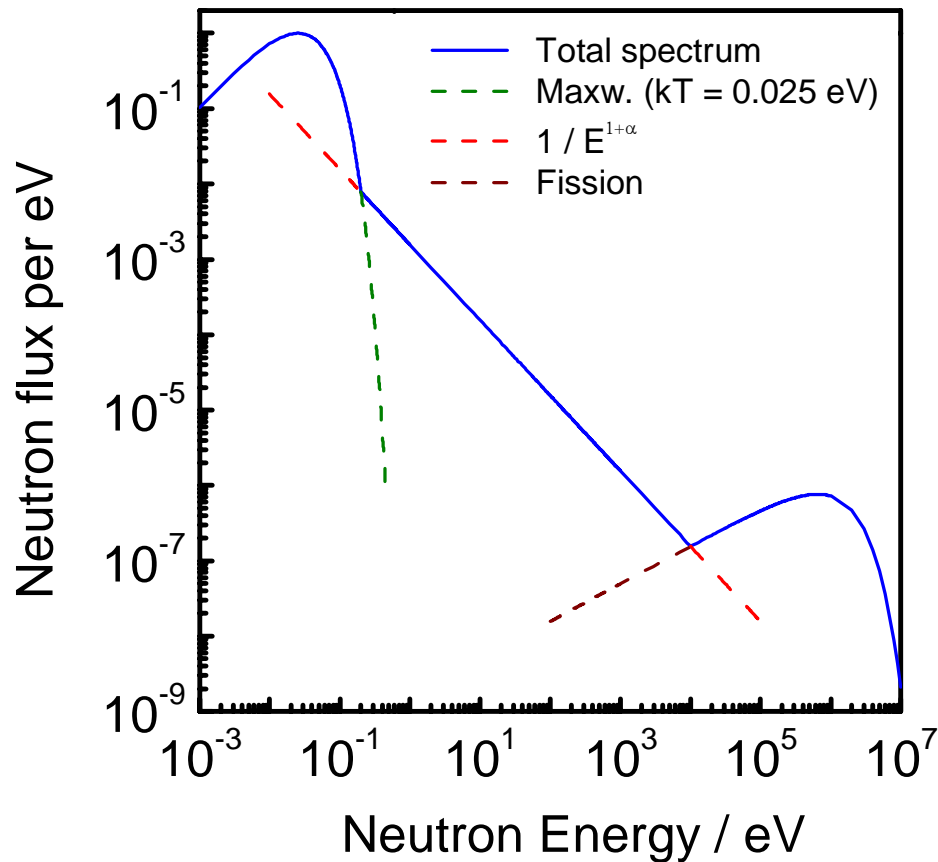

The total reaction rate per atom:

$$R = \int_0^{\infty} \phi(E_n) \sigma_{\gamma}(E_n) dE_n$$

depends on:

- $\phi(E_n)$ the neutron flux and
- $\sigma_{\gamma}(E_n)$ the capture cross section

The neutron flux in a thermal reactor is a sum of three components

- Maxwellian distribution with maximum at $E_n = kT$
- $1/E^{1+\alpha}$ distribution due to moderation process of the fast neutrons (epi-thermal spectrum)
- “Watt spectrum” of fission neutrons

At a neutron guide, the neutron flux can be described by the thermal part only (e.g. PGAA at Budapest)

The total reaction rate per atom is:

$$R = \int_0^{\infty} \phi(E_n) \sigma(E_n) dE_n$$

To solve the integral one separates between the thermal and the epi-thermal region:

$$R = \int_0^{\infty} \sigma(E) \phi(E) dE = \int_0^{E_{cd}} \sigma(E) \phi(E) dE + \int_{E_{cd}}^{\infty} \sigma(E) \phi(E) dE$$

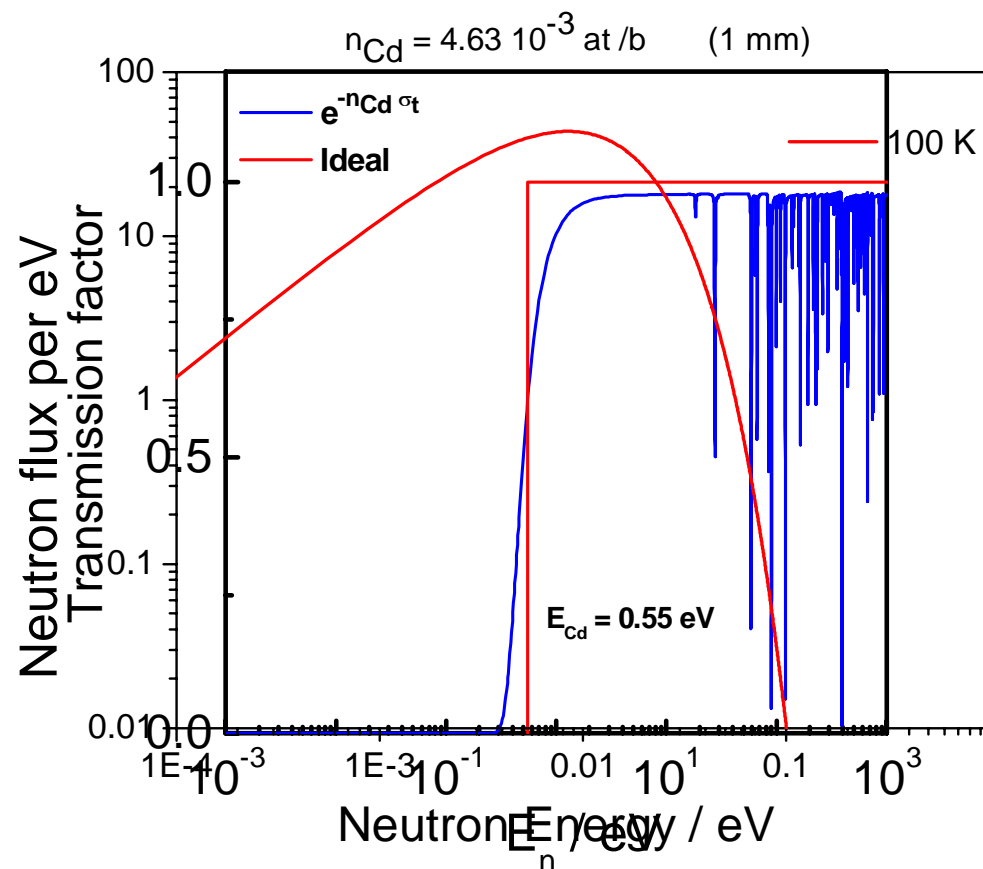

with $E_{cd} = 0.55 \text{ eV}$

Guided beam

$$R = \int_0^{E_{cd}} \sigma(E) \phi(E) dE$$

Cd measurement

$$R = \int_{E_{cd}}^{\infty} \sigma(E) \phi(E) dE$$

$$R = \int_0^{\infty} \sigma(E) \varphi(E) dE = \int_0^{E_{cd}} \sigma(E) \varphi(E) dE + \int_{E_{cd}}^{\infty} \sigma(E) \varphi(E) dE$$

$$R = \varphi_t \sigma_0 g_w G_{th} + \varphi_e I_r G_r = \varphi_t \sigma_0 \left(g_w G_{th} + \frac{1}{f} \frac{I_r}{\sigma_0} G_r \right)$$

- φ_t thermal flux
- σ_0 thermal cross section at $v=2200$ m/s
- g_w generalized g-factor: deviation of the cross section from $1/v$
- G_{th} thermal flux depression factor
- φ_e epithermal flux
- I_r effective resonance integral
- G_r resonance self-shielding factor
- f ratio of thermal to epithermal flux
- $Q=I_r/\sigma_0$ ratio of the resonance integral and thermal cross section

$$\int_0^{E_{cd}} \sigma(E) \phi(E) dE = \phi_t \sigma_0 g_w G_t$$

depends on the geometry,
composition (σ)

$$\phi_t = \frac{2}{\sqrt{\pi}} \int_0^{E_{cd}} \phi(E) dE$$

$$\sigma_{th} = \frac{\int_0^{E_{cd}} \sigma(E) \phi(E) dE}{\int_0^{E_{cd}} \phi(E) dE}$$

$$g_w = \frac{\int_0^{E_{cd}} \sigma(E) \phi(E) dE}{\frac{\sqrt{\pi}}{2} \phi_t \sigma_0} = \frac{\int_0^{E_{cd}} \sigma(E) \phi(E) dE}{\sigma_0 \int_0^{E_{cd}} \phi(E) dE} = \frac{2}{\sqrt{\pi}} \frac{\sigma_{th}}{\sigma_0}$$

$$g_w = \frac{\int_0^{E_{cd}} \sigma(E) \varphi(E) dE}{\frac{\sqrt{\pi}}{2} \varphi_t \sigma_0} = \frac{\int_0^{E_{cd}} \sigma(E) \varphi(E) dE}{\sigma_0 \int_0^{E_{cd}} \varphi(E) dE} = \frac{2}{\sqrt{\pi}} \frac{\sigma_{th}}{\sigma_0}$$

g_w depends on:

Flux shape (may not be Maxwellian)

Cross section shape (may not be $1/v$)

If the flux has a Maxwellian distribution and If the cross section is $1/v$

$$\sigma_{th} = \frac{\sqrt{\pi}}{2} \sigma_0 \sqrt{\frac{T_0}{T}} \quad \Rightarrow \quad g_w = \sqrt{\frac{T_0}{T}}$$

The Westcott g_w – factor is temperature dependent

$$R = \varphi_t \sigma_0 g_w G_{th} + \varphi_e I_r G_r$$

$$\varphi_e I_r G_r = \int_{E_{cd}}^{\infty} \sigma(E) \varphi(E) dE$$

$$\varphi_e = \int_{E_{cd}}^{\infty} \varphi(E) dE$$

Resonance integral

I_r depends on:

$\sigma(E)$ (resonance parameters)

$\varphi(E)$ (e.g. $E^{-(1+\alpha)}$)

$$I_r = \frac{\int_{E_{cd}}^{\infty} \sigma(E) \varphi(E) dE}{\varphi_e}$$

**Data base of σ_0 , g_w -factor and I_r

resonance integrals and g_w -factors”**

INDC(NDS) – 440

February 2003

So far, one atom
Real case N atoms

$$R_N = N\phi_t\sigma_0 \left(g_w G_{th} + \frac{1}{f} \frac{I_r}{\sigma_0} G_r \right)$$

R_N from measurement

Knowing N, we can deduce σ (nuclear data)

Knowing σ (nuclear data), we can deduce N

How to measure the R_N

- Sample activation by neutron irradiation in reactor
- The sample is transferred into a counting station (Rabbit system)
- (Waiting time)
- Counting
- Isotope identification by means of the γ -ray energy
- High resolution detector needed
 - Ge(Li), HPGe
 - NaI
- Peak analysis
- Correlate peak area with R , isotope abundance

Simple reaction/decay (no branching...)

$$C_{\gamma} = \frac{N_{av} W \theta}{M} P_{\gamma} \varepsilon_{FE} t_m R \left(1 - e^{-\lambda t_i}\right) e^{-\lambda t_d} \frac{\left(1 - e^{-\lambda t_m}\right)}{e^{-\lambda t_m}}$$

NAA for Non Destructive Analysis

$$W = \frac{C_{\gamma}}{t_m \left(1 - e^{-\lambda t_i}\right) e^{-\lambda t_d} \frac{\left(1 - e^{-\lambda t_m}\right)}{e^{-\lambda t_m}}} \frac{M}{N_{av} \theta} \frac{1}{R P_{\gamma} \varepsilon_{FE}}$$

C_{γ}	Counts (DT,coinc)
W	Sample mass
θ	Isotopic abundance
M	Molar mass
N_{av}	Avogadro's number
P	γ -ray intensity

$$R = \varphi_t \sigma_0 \left(g_w G_{th} + \frac{1}{f} \frac{I_r}{\sigma_0} G_r \right)$$

t_i	Irradation Time
t_d	Decay Time
t_m	Counting Time

- Absolute method (ε_{FE} , P_{γ} , σ_0 sources of uncertainty)

Relative abundance

$$\frac{W}{W_{\text{ref}}} = \frac{C_{\gamma}}{C_{\gamma,\text{ref}}} \frac{\varepsilon_{\text{FE,ref}}}{\varepsilon_{\text{FE}}} \frac{G_t g_w + G_f \frac{Q}{f}}{G_{t,\text{ref}} g_{w,\text{ref}} + G_{f,\text{ref}} \frac{Q_{\text{ref}}}{f}} \frac{\sigma_{0,\text{ref}}}{\sigma_0} \frac{M}{M_{\text{ref}}} \frac{\theta_{\text{ref}} P_{\gamma,\text{ref}}}{\theta P_{\gamma}}$$

Reference $^{197}\text{Au}(n,\gamma) E_{\gamma}=411.8 \text{ keV}$

k_0

accurately determined for many nuclides
depends only on the isotope

e.g. De Corte/Simonits (JRNC 133 (1989) 43)

$$\frac{1}{k_0} = \frac{\sigma_{0,\text{ref}}}{\sigma_0} \frac{M}{M_{\text{ref}}} \frac{\theta_{\text{ref}} P_{\gamma,\text{ref}}}{\theta P_{\gamma}}$$

N.B. It is actually a cross section measurement!

Relative abundance

$$\frac{W}{W_{\text{ref}}} = \frac{C_{\gamma}}{C_{\gamma,\text{ref}}} \frac{\varepsilon_{\text{FE,ref}}}{\varepsilon_{\text{FE}}} \frac{G_{\text{t}}g_{\text{w}} + G_{\text{f}}\frac{Q}{f}}{G_{\text{t,ref}}g_{\text{w,ref}} + G_{\text{f,ref}}\frac{Q_{\text{ref}}}{f}} \frac{1}{k_0}$$

Usually a ^{197}Au sample is co-irradiated with the sample to analyse

Experimental conditions

- ε_{FE}
- $\varphi(E)$ Q, g_{w}, f
- geometry G

Microscopic data

- $\sigma(E)$ Q, g_{w}, k_0

$$\frac{G_{\text{t}}g_{\text{w}} + G_{\text{f}}\frac{Q}{f}}{G_{\text{t,ref}}g_{\text{w,ref}} + G_{\text{f,ref}}\frac{Q_{\text{ref}}}{f}}$$

 - Compton suppression system
 - Remarks

- **Examples**

Neutron Induced Prompt Gamma Activation Analyses (PGAA or PGNAA)

- **Detection of prompt gamma radiation from a neutron induced nuclear reaction, usually radiative capture**
- **Isotope identification based on E_{γ}**
- **Isotope quantification based on I_{γ}**
- **Instantaneous method: results appear immediately**
- **Usually little or negligible residual activation of the sample**

The total reaction rate per atom:

$$R = \int_0^{\infty} \varphi(E_n) \sigma_{\gamma}(E_n) dE_n$$

depends on:

$\varphi(E_n)$ the neutron flux and
 $\sigma_{\gamma}(E_n)$ the capture cross section

For a guided (thermal or cold) neutron beam $R = G_{th} \varphi_t \sigma_{\gamma 0} g_w$

If we look at a given transition

$$R_i = G_{th} \phi_t \sigma_{\gamma 0, i} g_w = G_{th} \phi_t P_{\gamma} \sigma_{\gamma 0} g_w$$

where P_{γ} is the intensity of the transition

for N atoms

$$R_{N, i} = N G_{th} \phi_t P_{\gamma} \sigma_{\gamma 0} g_w$$

$R_{N, i}$ from measurement

Knowing N , we can deduce σ (nuclear data)

Knowing σ (nuclear data), we can deduce N

How to measure the R_N

- Sample by neutron irradiation (e.g. cold neutron beam)
- Counting
- Isotope identification by means of the γ -ray energy
- High resolution detector needed
 - Ge(Li), HPGe
 - NaI
- Peak analysis
- Correlate peak area with R , isotope abundance

non radioactive nucleus

$$C_{\gamma} = \frac{N_{av} W \theta}{M} P_{\gamma} \sigma_{\gamma 0} g_w G_{th} \varepsilon_{FE} t_m \phi_t$$

PGAA for Non Destructive Analysis

$$W = \frac{C_{\gamma}}{\varepsilon_{FE} t_m} \frac{M}{N_{av} \theta} \frac{1}{G_{th} \phi_t P_{\gamma} \sigma_{\gamma 0} g_w}$$

– Absolute method (large uncertainties)

C_{γ}	Counts (DT,coinc)
P_{γ}	γ -ray intensity
ε_{FE}	Full Energy peak detection efficiency
W	Sample mass
θ	Isotopic abundance
M	Molar mass
t_m	Counting Time

Relative measurements allow to reduce the uncertainty

– comparator (ref)

$$\frac{W}{W_{\text{ref}}} = \frac{C_{\gamma}}{C_{\gamma,\text{ref}}} \frac{\varepsilon_{\text{FE,ref}}}{\varepsilon_{\text{FE}}} \frac{g_w}{g_{w,\text{ref}}} \frac{\sigma_{0,\text{ref}}}{\sigma_0} \frac{M}{\theta P_{\gamma}} \frac{\theta_{\text{ref}} P_{\gamma,\text{ref}}}{M_{\text{ref}}} \rightarrow \frac{1}{k_0}$$

– homogeneous sample $\Rightarrow G$ is the same

– efficiency ratio can be determined accurately (<1%)

– method standardization (Revay and Molnar, Radiochimica Acta 91, 361, 2003):

– k_0, σ_0 library

– Ultimate comparator: H $\sigma_0 = 0.3326(7)$ b, 2.2 MeV

\Rightarrow no standard samples needed

Cold Neutron Beam

Compton Suppression System

$\varphi_{th,eq} \sim 5 \times 10^7 \text{ n/cm}^2\text{s}$

Sample

CANBERRA

Why using a cold beam?

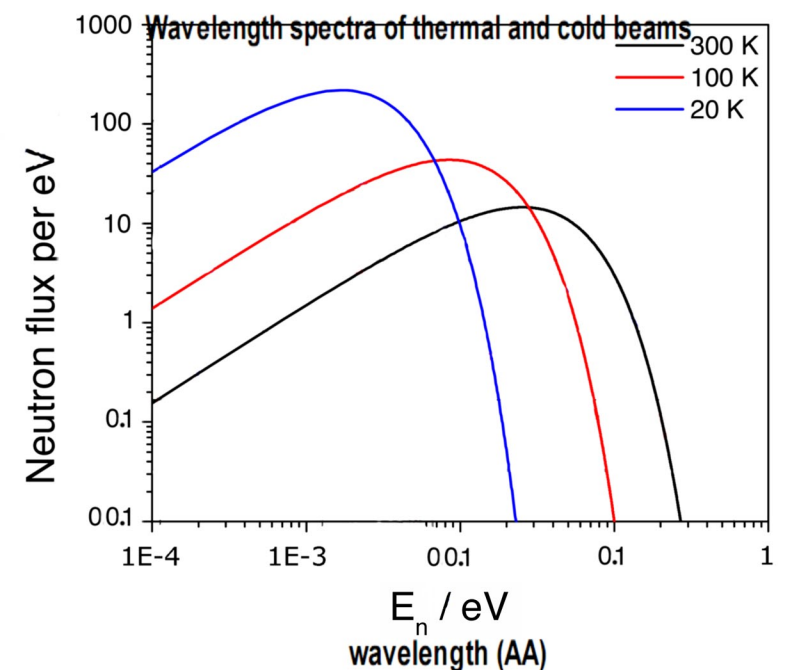

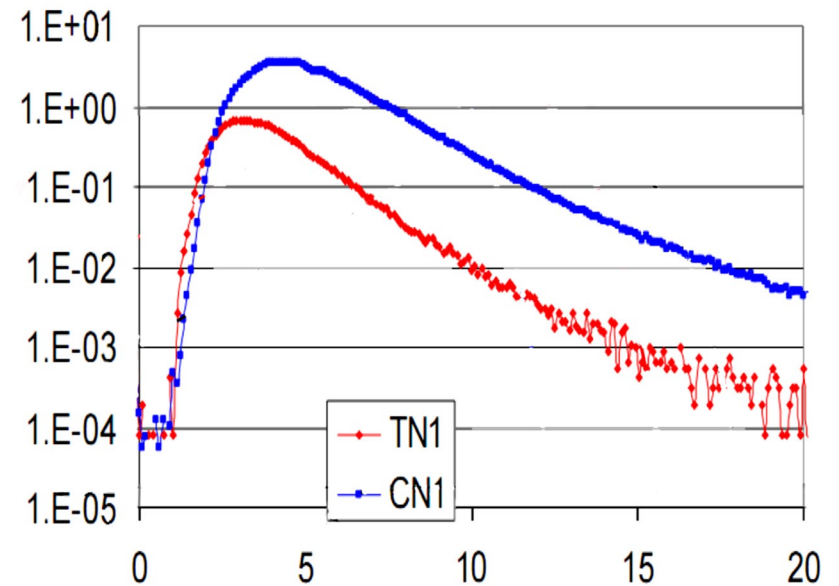

More neutron with lower energy

Cross section is higher

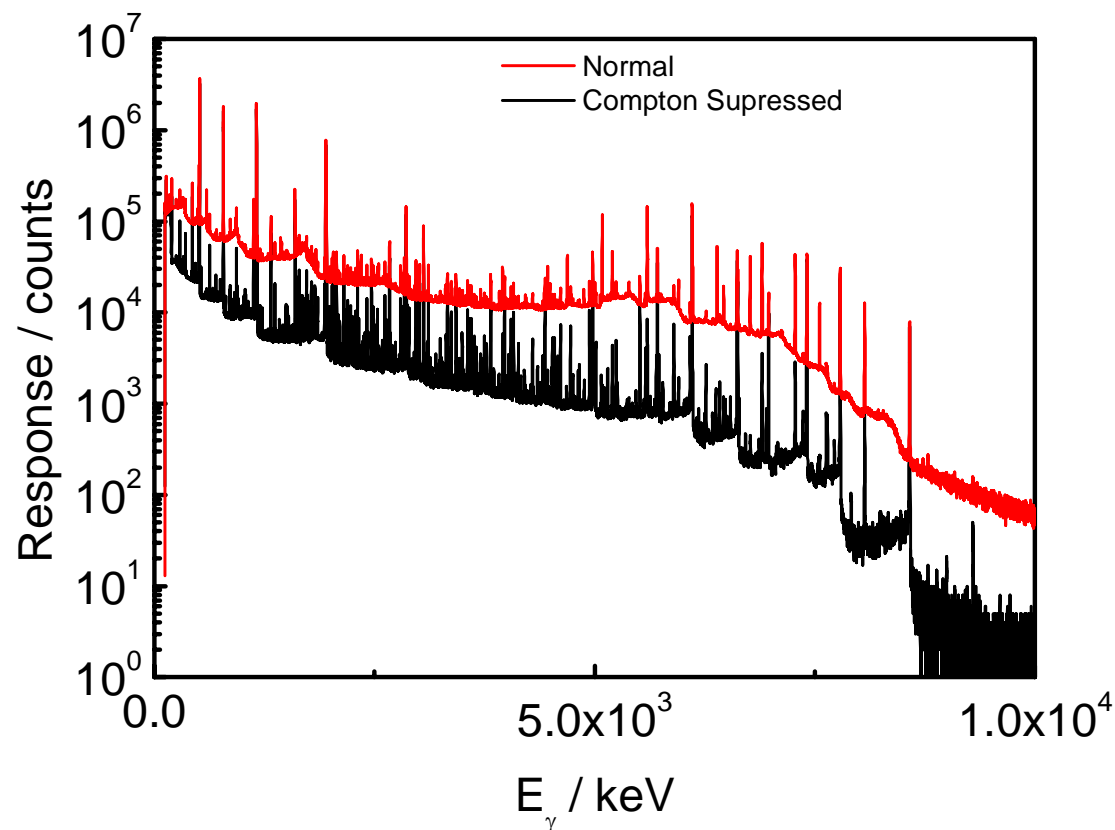

The count rate is higher

No epithermal neutrons

g_w is 1 in most cases

Why using Compton suppression system?

Peak to background improved

- **Neutron capture cross section measurements**
 - ^{nat}Pb , ^{206}Pb , ^{209}Bi , ^{127}I , ^{129}I ...
- **Rocks and minerals (Geology, Archaeology)**
 - lapislazuli composition (Cl, S content) \Rightarrow ore
- **Ceramics (Archaeology)**
- **Glasses Metals (Archaeology, Industry)**
 - Roman silver coins Cu/Ag ratio \Rightarrow period
- **Chemistry**
 - S in fullerene (C_{60})
- **Metals (Materials Research, Archaeology)**
- **Nuclear Materials (Safeguards, Transmutation)**
 - $^{235}\text{U}/^{238}\text{U}$ mass ratio

Pros:

- Multi elemental method
- Applicable in principle to all elements
- No special sample preparation

Cons:

- γ -ray spectra more complex than NAA

Data needed:

- g_w
- k_0
- OR
- Thermal cross sections (Partial cross sections)

PGAA detection limits

- Principle
 - Resonances for analysis of elemental composition
 - NRCA and NRT
- Data Analysis
 - Calibration approach
 - Methodological approach
- Applications
- NRA and PGAA
- ND for NRA
- Conclusions

- Neutron resonances appear at given energies, specific for each nuclide
- Nuclides can be identified and the elemental (and isotopic) composition can be deduced
- Applicable for almost all elements
- No sample preparation required
- Non - Destructive
- Negligible residual activation

(I)NAA

Intense thermal neutron flux (irradiation in core, i.e. BR1)

Gamma detector: gamma ray energy resolution \Rightarrow Ge-detectors

PGNAA

Intense neutron beam, (guided cold neutron beam Budapest, NIST)

Gamma detector: gamma ray energy resolution \Rightarrow Ge-detectors

NRA

Pulsed white neutron beam (LINAC)

Gamma detector: good time resolution \Rightarrow scintillators

Pulsed Neutron Beam
White Neutron Energy
Spectrum

TOF $\Leftrightarrow E_n$

$$E_n = \frac{1}{2} m_n v_n^2 = \frac{1}{2} m_n \left(\frac{L}{t} \right)^2$$

Good time resolution
High neutron flux

Intensity

$$\varphi_n(E_n) \propto \frac{1}{L^2}$$

$L \uparrow \Rightarrow \varphi_n \downarrow$

Resolution

$$R_n = \frac{\Delta E_n}{E_n} = 2 \sqrt{\frac{\Delta T_n}{T_n} + \frac{\Delta L}{L}}$$

$L \uparrow \Rightarrow R_n \downarrow$

Intensity

$$\varphi_n(E_n) \propto \frac{1}{L^2}$$

$$L \uparrow \Rightarrow \varphi_n \downarrow$$

Resolution

$$R_n = \frac{\Delta E_n}{E_n} = 2 \sqrt{\frac{\Delta T_n}{T_n} + \frac{\Delta L}{L}}$$

$$L \uparrow \Rightarrow R_n \downarrow$$

⁴⁰Ca resonances

Detector

$$T = \frac{C_{in}}{C_{out}} \approx e^{-n\sigma_{tot}}$$

no correction for efficiency

no normalisation required

but good collimation required

- All detected neutrons must have crossed the sample
- All neutrons scattered by the sample may not reach the detector

low sensitivity (exponential + potential scattering)

$$R_c = \varepsilon_c n_x \sigma_\gamma F \phi S$$

- ε_c detection efficiency for capture event
- n_x number of nuclei per cm^2 for nuclide x
- σ_c capture cross section
- F** self-shielding factor
- S** Effective area
- ϕ neutron flux

$$F = \left(\frac{1 - e^{-n\sigma_t}}{n\sigma_t} \right)$$

More sensitive but the data analysis is more complicated

NRCA

Gamma Detectors - C_6D_6 , YAP

Good time resolution (1 ns)

Low neutron sensitivity

NRT

Neutron Detectors - Li glass

NE905

Good time resolution

PSND (developed at CCLRC)

⇒ we can always define a region in the TOF (Energy) - spectrum where the resonance of interest dominates

Traditional approach Area analysis

$$R_c = \varepsilon_c n_x \sigma_\gamma F \phi S \quad \Rightarrow \quad C_c = \varepsilon_c n_x A_\gamma F \phi S$$

⇒ only isolated resonances are used

Only valid for relatively weak resonances

neglect neutron scattering in the sample

Calibration

requires representative calibration samples to determine unknown and F

Limited in applications (no complex spectra, samples,...)

Limited use of information contained within the spectrum

However, **Very successful (e.g. Archeology, H. Postma)**

$$\frac{C_{r1,x}}{C_{r2,y}} = \frac{\varepsilon_{r1,x}}{\varepsilon_{r2,y}} \frac{F_{r1}}{F_{r2}} \frac{A_{\gamma,r1}}{A_{\gamma,r2}} \frac{\varphi_{r1}}{\varphi_{r2}} \frac{n_x}{n_y}$$

$$A_{\gamma,r} = 4.097 \times 10^6 \frac{g\Gamma_n\Gamma_\gamma}{E_r\Gamma} \text{ (b)}$$

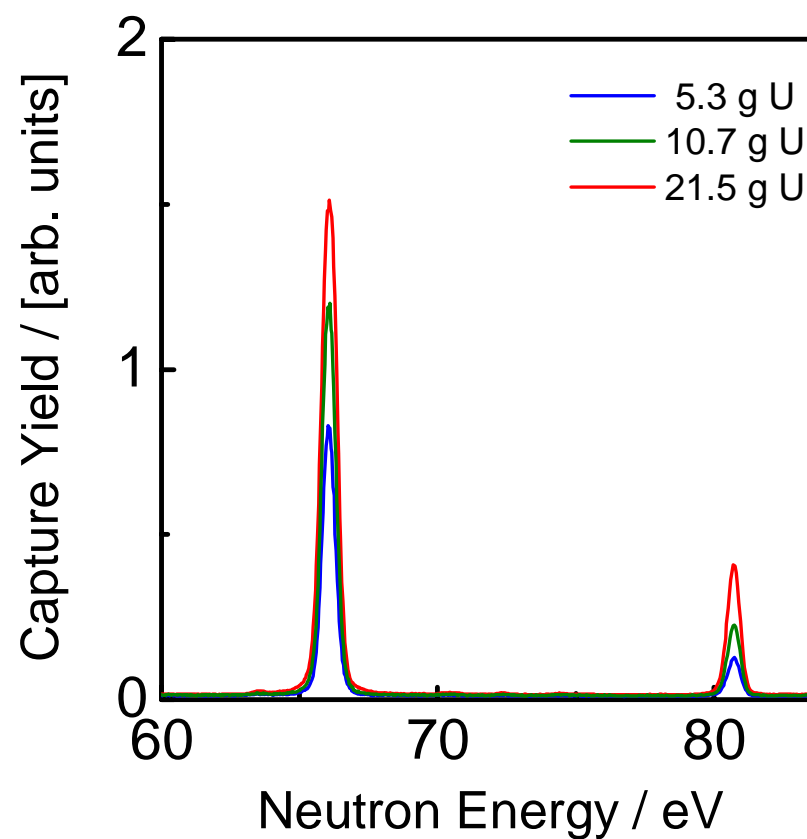

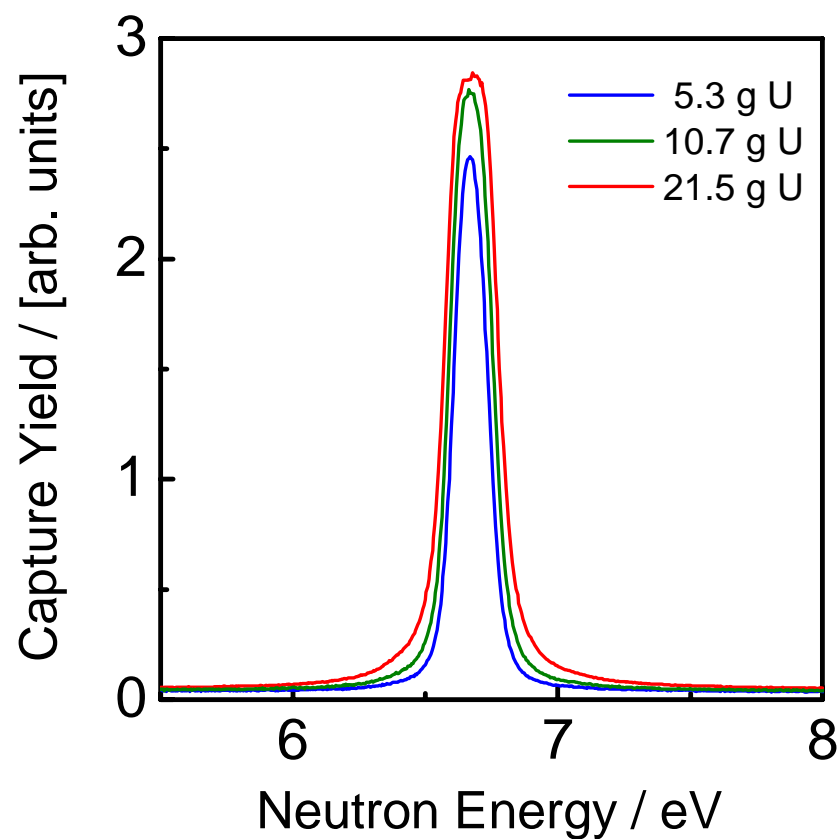

- **φ neutron flux ($\varphi_{r1} / \varphi_{r2}$) (only shape required!!)**
 \Rightarrow Independent measurement by e.g. $^{10}\text{B}(n,\alpha)^7\text{Li}$
- **Resonance capture area ($A_{\gamma,r1}$ & $A_{\gamma,r2}$)**
 \Rightarrow From nuclear data libraries
- **ε detection efficiency for capture event ($\varepsilon_{r1} / \varepsilon_{r2}$)**
 \Rightarrow By calibration with standard samples (no correction for attenuation in sample)
- **Self - shielding factors (F_{r1} / F_{r2})**
 \Rightarrow From combination of at least two resonances, with different strength

$$F_r = \left(\frac{1 - e^{-n\sigma_t}}{n\sigma_t} \right)$$

$n\sigma_t \ll 1 \Rightarrow F \cong 1$

for main elements use weaker resonances

for traces use stronger resonances

\Rightarrow Thickness (n) from combination of resonances with different strength !!!

F_r from ratio of resonances with different strength

$$\frac{C_{r1,x}}{C_{r2,y}} = \frac{\varepsilon_{r1,x}}{\varepsilon_{r2,y}} \frac{\varphi_{r1}}{\varphi_{r2}} \frac{A_{\gamma,r1}}{A_{\gamma,r2}} \frac{F_{r1}(n_x, \sigma_{t1})}{F_{r2}(n_y, \sigma_{t2})}$$

independent of n

$$F_r = \left(\frac{1 - e^{-n\sigma_t}}{n\sigma_t} \right)$$

$$\frac{C_{r1,x}}{C_{r2,x}} = \frac{1}{K} f(n_x, \sigma_{t,r1}, \sigma_{t,r2})$$

Sn

230 eV ^{65}Cu
 650 eV ^{63}Cu
 994 eV ^{63}Cu
 1363 eV ^{65}Cu

NRCA requires capture yield, Y_c

Correction for the shape of the incoming neutron flux

Account for detection efficiency of the gamma event

(PHWT \Rightarrow NIM A 577 (2007) 626-640)

Advantages:

Resonance Shape Analysis (R-matrix) vs area analysis

Correction for self - shielding and multiple scattering

Resolution of TOF - spectrometer and Doppler broadening

The whole energy spectrum can be used to assess the nuclide abundance

Simultaneous fit of several data sets (both NRT and NRCA)

Easy to handle multi-elemental homogenous samples

G is an analytical model describing the observed capture yield:

$$Y_c = G(R, T, RP, F, \mu, S_x^*, n_x, S_y^*, n_y, \dots)$$

- R resolution of spectrometer
- T temperature (Doppler broad.)
- RP nuclear data to deduce σ_c, σ_t
- F self - shielding
- μ multiple scattering
- S_x^* binding energy nucleus x
- n_x atom density of nucleus x

⇒ n_x, n_y, \dots : adjustable fitting parameters

PGAA (at Budapest) and NRCA (at GELINA) Accuracy for Cu in a bronze artefact about 1%

$\Rightarrow k_0$ and C_r relative to Cu

PGAA best for light elements

H, S, P, and K

NRCA best for heavy elements

As, Ag, Sb, Au and Pb

Both NRCA and PGAA are fully non-destructive methods for bulk analysis

The residual activation is negligible, especially for NRCA

PGAA is good for light elements, NRCA better for heavy elements

PGAA can be hampered by an unfavourable balance between the thermal capture cross sections of the elements
 \Rightarrow for NRCA we can always choose a region in the TOF-spectrum where the resonance of interest dominates

Pros:

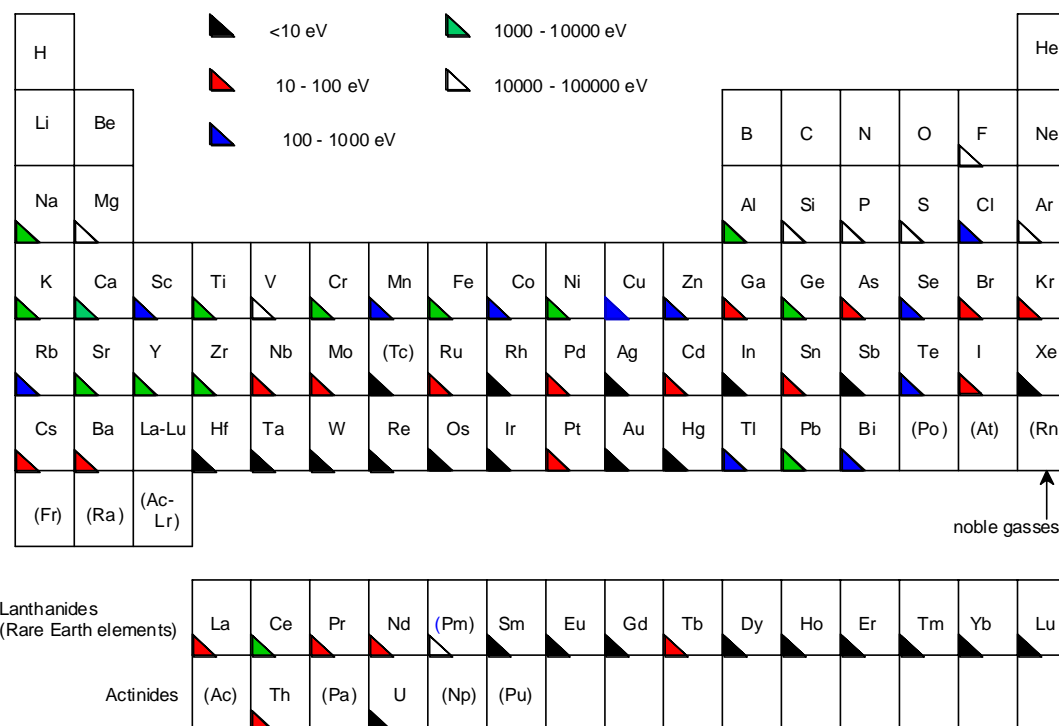

- Multi elemental method
- Applicable to all elements with resonances
- No special sample preparation
- Negligible residual activation

Cons:

- Data analysis not easy
- Additional measurements with methodological approach

Data needed:

- A_γ
- OR
- Resonance Parameters $\Rightarrow \sigma_\gamma(E), \sigma_t(E)$

The probability that a neutron interacts with a nucleus is expressed as a cross section σ , which has the dimension of an area
The unit of a cross section is taken as :
1 barn, 1 b = 10^{-24} cm^2

The total reaction rate per atom:

$$R = \int_0^{\infty} \varphi(E_n) \sigma_{\gamma}(E_n) dE_n$$

depends on:

$\varphi(E_n)$ the neutron flux and
 $\sigma_{\gamma}(E_n)$ the capture cross section

The neutron flux in a thermal reactor is a sum of three components

- Maxwellian distribution with maximum at $E_n = kT$
- $1/E^{1+\alpha}$ distribution due to moderation process of the fast neutrons (epi-thermal spectrum)
- “Watt spectrum” of fission neutrons

At a neutron guide, the neutron flux can be described by the thermal part only (e.g. PGAA at Budapest)

The total reaction rate per atom is:

$$R = \int_0^{\infty} \varphi(E_n) \sigma(E_n) dE_n$$

To solve the integral one separates between the thermal and the epi-thermal region:

$$R = \int_0^{\infty} \sigma(E) \varphi(E) dE = \int_0^{E_{cd}} \sigma(E) \varphi(E) dE + \int_{E_{cd}}^{\infty} \sigma(E) \varphi(E) dE$$

with $E_{cd} = 0.55 \text{ eV}$

Guided beam

$$R = \int_0^{E_{cd}} \sigma(E)\phi(E)dE$$

Cd measurement

$$R = \int_{E_{cd}}^{\infty} \sigma(E)\phi(E)dE$$

Guided beam

$$R = \int_0^{E_{cd}} \sigma(E)\phi(E)dE$$

Cd measurement

$$R = \int_{E_{cd}}^{\infty} \sigma(E)\phi(E)dE$$

$$R = \int_0^{\infty} \sigma(E)\varphi(E)dE = \int_0^{E_{cd}} \sigma(E)\varphi(E)dE + \int_{E_{cd}}^{\infty} \sigma(E)\varphi(E)dE = R_{th} + R_{epi}$$

$$R_{th} = \varphi_t \sigma_0 g_w G_{th}$$

- φ_t thermal flux
- σ_0 thermal cross section at $v=2200$ m/s
- g_w generalized g-factor: deviation of the cross section from $1/v$
- G_{th} thermal flux depression factor

$$R = \int_0^{\infty} \sigma(E)\varphi(E)dE = \int_0^{E_{cd}} \sigma(E)\varphi(E)dE + \int_{E_{cd}}^{\infty} \sigma(E)\varphi(E)dE = R_{th} + R_{epi}$$

$$R_{epi} = \varphi_e I_r G_r = \varphi_t \sigma_0 \frac{1}{f} \frac{I_r}{\sigma_0} G_r$$

φ_e epithermal flux

I_r effective resonance integral

G_r resonance self-shielding factor

f ratio of thermal to epithermal flux

$Q=I_r/\sigma_0$ ratio of the resonance integral and thermal cross section

$$R_{th} = \int_0^{E_{cd}} \sigma(E) \phi(E) dE = \phi_t \sigma_0 g_w G_t$$

depends on the geometry,
composition (σ)

$$\phi_t = \frac{2}{\sqrt{\pi}} \int_0^{E_{cd}} \phi(E) dE$$

$$\sigma_{th} = \frac{\int_0^{E_{cd}} \sigma(E) \phi(E) dE}{\int_0^{E_{cd}} \phi(E) dE}$$

$$g_w = \frac{\int_0^{E_{cd}} \sigma(E) \phi(E) dE}{\frac{\sqrt{\pi}}{2} \phi_t \sigma_0} = \frac{\int_0^{E_{cd}} \sigma(E) \phi(E) dE}{\sigma_0 \int_0^{E_{cd}} \phi(E) dE} = \frac{2}{\sqrt{\pi}} \frac{\sigma_{th}}{\sigma_0}$$

$$g_w = \frac{\int_0^{E_{cd}} \sigma(E) \varphi(E) dE}{\frac{\sqrt{\pi}}{2} \varphi_t \sigma_0} = \frac{\int_0^{E_{cd}} \sigma(E) \varphi(E) dE}{\sigma_0 \int_0^{E_{cd}} \varphi(E) dE} = \frac{2}{\sqrt{\pi}} \frac{\sigma_{th}}{\sigma_0}$$

g_w depends on:

Flux shape (may not be Maxwellian)

Cross section shape (may not be $1/v$)

If the flux has a Maxwellian distribution and If the cross section is $1/v$

$$\sigma_{th} = \frac{\sqrt{\pi}}{2} \sigma_0 \sqrt{\frac{T_0}{T}} \Rightarrow g_w = \sqrt{\frac{T_0}{T}}$$

The Westcott g_w – factor is temperature dependent

$$R = \varphi_t \sigma_0 g_w G_{th} + \varphi_e I_r G_r$$

$$\varphi_e I_r G_r = \int_{E_{cd}}^{\infty} \sigma(E) \varphi(E) dE$$

$$\varphi_e = \int_{E_{cd}}^{\infty} \varphi(E) dE$$

Resonance integral

I_r depends on:

$\sigma(E)$ (resonance parameters)

$\varphi(E)$ (e.g. $E^{-(1+\alpha)}$)

$$I_r = \frac{\int_{E_{cd}}^{\infty} \sigma(E) \varphi(E) dE}{\varphi_e}$$

**Data base of σ_0 , g_w -factor and I_r

resonance integrals and g_w -factors”**

INDC(NDS) – 440

February 2003

So far, one atom
Real case N atoms

$$R_N = N\phi_t\sigma_0 \left(g_w G_{th} + \frac{1}{f} \frac{I_r}{\sigma_0} G_r \right)$$

R_N from measurement

Knowing N, we can deduce σ (nuclear data)

Knowing σ (nuclear data), we can deduce N

How to measure the R_N

- Sample activation by neutron irradiation in reactor
- The sample is transferred into a counting station (Rabbit system)
- (Waiting time)
- Counting
- Isotope identification by means of the γ -ray energy
- High resolution detector needed
 - Ge(Li), HPGe
 - NaI
- Peak analysis
- Correlate peak area with R , isotope abundance

Simple reaction/decay (no branching...)

$$C_{\gamma} = \frac{N_{av} W \theta}{M} P_{\gamma} \varepsilon_{FE} R (1 - e^{-\lambda t_i}) e^{-\lambda t_d} \frac{(1 - e^{-\lambda t_m})}{\lambda}$$

NAA for Non Destructive Analysis

$$W = \frac{C_{\gamma} M}{(1 - e^{-\lambda t_i}) e^{-\lambda t_d} \frac{(1 - e^{-\lambda t_m})}{\lambda} N_{av} \theta R P_{\gamma} \varepsilon_{FE}}$$

C_{γ}	Counts (DT,coinc)
W	Sample mass
θ	Isotopic abundance
M	Atomic mass
N_{av}	Avogadro's number
P	γ -ray intensity

$$R = \varphi_t \sigma_0 \left(g_w G_{th} + \frac{1}{f} \frac{I_r}{\sigma_0} G_r \right)$$

t_i	Irradiation Time
t_d	Decay Time
t_m	Counting Time

- Absolute method (ε_{FE} , P_{γ} , σ_0 sources of uncertainty)

Relative abundance

$$\frac{W}{W_{\text{ref}}} = \frac{C_{\gamma}}{C_{\gamma,\text{ref}}} \frac{\varepsilon_{\text{FE,ref}}}{\varepsilon_{\text{FE}}} \frac{G_{\text{t}}g_{\text{w}} + G_{\text{f}} \frac{Q}{f}}{G_{\text{t,ref}}g_{\text{w,ref}} + G_{\text{f,ref}} \frac{Q_{\text{ref}}}{f}} \frac{\sigma_{0,\text{ref}}}{\sigma_0} \frac{M}{M_{\text{ref}}} \frac{\theta_{\text{ref}} P_{\gamma,\text{ref}}}{\theta P_{\gamma}}$$

Reference $^{197}\text{Au}(n,\gamma) E_{\gamma}=411.8 \text{ keV}$

k_0

accurately determined for many nuclides
depends only on the isotope

e.g. De Corte/Simonits (JRNC 133 (1989) 43)

$$\frac{1}{k_0} = \frac{\sigma_{0,\text{ref}}}{\sigma_0} \frac{M}{M_{\text{ref}}} \frac{\theta_{\text{ref}} P_{\gamma,\text{ref}}}{\theta P_{\gamma}}$$

N.B. It is actually a cross section measurement!

Relative abundance

$$\frac{W}{W_{\text{ref}}} = \frac{C_{\gamma}}{C_{\gamma,\text{ref}}} \frac{\varepsilon_{\text{FE,ref}}}{\varepsilon_{\text{FE}}} \frac{G_{\text{t}}g_{\text{w}} + G_{\text{f}}\frac{Q}{f}}{G_{\text{t,ref}}g_{\text{w,ref}} + G_{\text{f,ref}}\frac{Q_{\text{ref}}}{f}} \frac{1}{k_0}$$

Usually a ^{197}Au sample is co-irradiated with the sample to analyse

Experimental conditions

- ε_{FE}
- $\varphi(E)$ Q, g_{w}, f
- geometry G

$$\frac{G_{\text{t}}g_{\text{w}} + G_{\text{f}}\frac{Q}{f}}{G_{\text{t,ref}}g_{\text{w,ref}} + G_{\text{f,ref}}\frac{Q_{\text{ref}}}{f}}$$

 - Examples (^{209}Bi , ^{206}Pb)

Neutron Induced Prompt Gamma Activation Analyses (PGAA or PGNAA)

- **Detection of prompt gamma radiation from a neutron induced nuclear reaction, usually radiative capture**
- **Isotope identification based on E_{γ}**
- **Isotope quantification based on I_{γ}**
- **Instantaneous method: results appear immediately**
- **Usually little or negligible residual activation of the sample**

The total reaction rate per atom:

$$R = \int_0^{\infty} \varphi(E_n) \sigma_{\gamma}(E_n) dE_n$$

depends on:

$\varphi(E_n)$ the neutron flux and
 $\sigma_{\gamma}(E_n)$ the capture cross section

For a guided (thermal or cold) neutron beam $R = G_{th} \varphi_t \sigma_{\gamma 0} g_w$

If we look at a given transition

$$R_i = G_{th} \varphi_t \sigma_{\gamma 0, i} g_w = G_{th} \varphi_t P_{\gamma} \sigma_{\gamma 0} g_w$$

where P_{γ} is the intensity of the transition

for N atoms

$$R_{N, i} = N G_{th} \varphi_t P_{\gamma} \sigma_{\gamma 0} g_w$$

$R_{N, i}$ from measurement

Knowing N , we can deduce σ (nuclear data)

Knowing σ (nuclear data), we can deduce N

How to measure the R_N

- We look at the prompt-gamma emission after neutron irradiation (e.g. cold neutron beam)
- Isotope identification by means of the γ -ray energy
- High resolution detector needed
 - Ge(Li), HPGe
 - NaI
- Peak analysis
- Correlate peak area with R , isotope abundance/ σ

Why using a cold beam?

More neutron with lower energy

Cross section is higher

The count rate is higher

No epithermal neutrons

g_w is 1 in most cases

Why using a cold beam?

More neutron with lower energy

Cross section is higher

The count rate is higher

No epithermal neutrons

g_w is 1 in most cases

Wavelength spectra of thermal and cold beams

Why using Compton suppression system?

Peak to background improved

non radioactive nucleus

$$C_{\gamma} = \frac{N_{av} W \theta}{M} P_{\gamma} \sigma_{\gamma 0} g_w G_{th} \varepsilon_{FE} t_m \varphi_t$$

	t_m	Counting Time

PGAA for Non Destructive Analysis

$$W = \frac{C_{\gamma}}{\varepsilon_{FE} t_m} \frac{M}{N_{av} \theta} \frac{1}{G_{th} \varphi_t P_{\gamma} \sigma_{\gamma 0} g_w}$$

– Absolute method (large uncertainties)

Relative measurements allow to reduce the uncertainty

– comparator (ref)

$$\frac{W}{W_{\text{ref}}} = \frac{C_{\gamma}}{C_{\gamma,\text{ref}}} \frac{\varepsilon_{\text{FE,ref}}}{\varepsilon_{\text{FE}}} \frac{g_w}{g_{w,\text{ref}}} \frac{\sigma_{0,\text{ref}}}{\sigma_0} \frac{M}{\theta P_{\gamma}} \frac{\theta_{\text{ref}} P_{\gamma,\text{ref}}}{M_{\text{ref}}} \rightarrow \frac{1}{k_0}$$

- homogeneous sample \Rightarrow G is the same
 - efficiency ratio can be determined accurately (<1%)
 - method standardization (Revay and Molnar, Radiochimica Acta 91, 361, 2003):
 - k_0, σ_0 library
 - Ultimate comparator: H $\sigma_0 = 0.3326(7)$ b, 2.2 MeV
- \Rightarrow no standard samples needed

- **Neutron capture cross section measurements**
 - ${}^{\text{nat}}\text{Pb}$, ${}^{206}\text{Pb}$, ${}^{209}\text{Bi}$, ${}^{127}\text{I}$, ${}^{129}\text{I}$...
- **Rocks and minerals (Geology, Archaeology)**
 - lapislazuli composition (Cl, S content) \Rightarrow ore
- **Ceramics (Archaeology)**
- **Glasses Metals (Archaeology, Industry)**
 - Roman silver coins Cu/Ag ratio \Rightarrow period
- **Chemistry**
 - S in fullerene (C_{60})
- **Metals (Materials Research, Archaeology)**
- **Nuclear Materials (Safeguards, Transmutation)**
 - ${}^{235}\text{U}/{}^{238}\text{U}$ mass ratio

non radioactive nucleus

$$C_{\gamma} = \frac{N_{av} W \theta}{M} P_{\gamma} \sigma_{\gamma 0} g_w G_{th} \epsilon_{FE} t_m \phi_t$$

$$n = \frac{N_{av} \theta W}{M}$$

Number of nuclei

$$\sigma_{\gamma} = P_{\gamma} \sigma_{\gamma 0}$$

Partial Capture cross section

- C_{γ} Counts (DT,coinc)
- P_{γ} γ -ray intensity
- ϵ_{FE} Full Energy peak detection efficiency
- W Sample mass
- θ Isotopic abundance
- M Atomic mass
- t_m Counting Time

non radioactive nucleus

$$C_{\gamma} = n \sigma_{\gamma} g_w G_{th} \varepsilon_{FE} t_m \varphi_t$$

}	C_{γ}	Counts (DT,coinc)
	σ_{γ}	Partial γ -ray cross section
	ε_{FE}	Full Energy peak detection efficiency
	W	Sample mass
	θ	Isotopic abundance
	M	Atomic mass
	t_m	Counting Time

PGAA for cross section measurements

$$\sigma_{\gamma} = \frac{C_{\gamma}}{\varepsilon_{FE} t_m} \frac{1}{n} \frac{1}{G_{th} \varphi_t g_w}$$

$$\sigma_{\gamma} = \frac{C_{\gamma}}{\varepsilon_{FE} t_m} \frac{1}{n} \frac{(\alpha_{\gamma} + 1)}{G_{th} \varphi_t g_w}$$

- Internal conversion coefficient, important for low energy transitions

Mixture

$$\frac{\sigma_{\gamma,1x}}{\sigma_{\gamma,2y}} = \frac{(P_{\gamma} \sigma_{\gamma 0})_1}{(P_{\gamma} \sigma_{\gamma 0})_2} = \frac{C_{\gamma,1} \varepsilon_{FE,2} n_y \alpha_{\gamma 1} + 1 g_{w,2}}{C_{\gamma,2} \varepsilon_{FE,1} n_x \alpha_{\gamma 2} + 1 g_{w,1}}$$

Relative partial cross section

Stoichiometric compounds

n_Y/n_X known

e.g. nitrate sample $Pb(NO_3)_2$, $Bi(NO_3)_3$, normalisation to $^{14}N(n_{th,\gamma})$ 1884 keV line

ε

Accounts also γ -ray attenuation in the sample, can be accessed experimentally with measurements on ad-hoc sample or with simulations (e.g. MCNP)

Adding partial cross section feeding/depopulating one state

For primary gamma's

$$\sigma_{\gamma 0} = \sum_{J_0} \sigma_{\gamma, i}$$

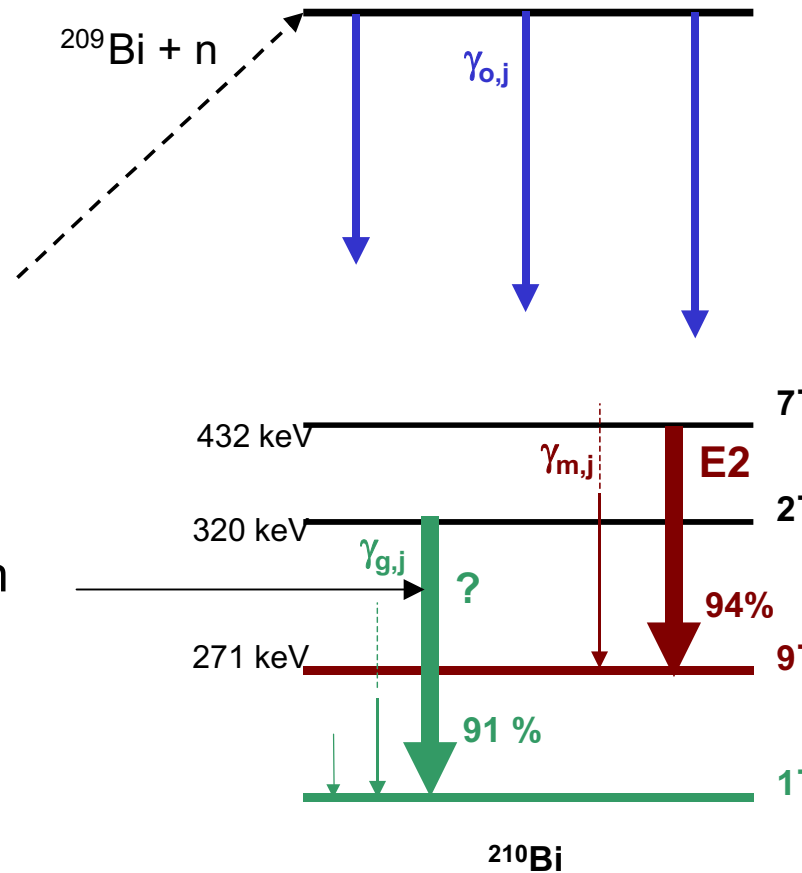

Gamma's to the ground state

$$\sigma_{\gamma 0, g} = \sum_{J_{gs}} \sigma_{\gamma, i}$$

Alternative method: Total energy (all observed gamma's)

$$\sum_{J=\text{all}} \sigma_{\gamma, i} E_{\gamma, i} = \sigma_{\gamma 0} E^*$$

320 keV transition
multipolarity unknown

- M1
- E2
- 50% E2 + 50% M1

$$\sigma_{m+g} = \sum_j \sigma_{\gamma_{0,j}}$$

$$\sigma_m = \sum_j \sigma_{\gamma_{m,j}}$$

$$\sigma_g = \sum_j \sigma_{\gamma_{g,j}}$$

Method	σ_{m+g} / mb	σ_m / mb	σ_g / mb	
Primary γ 's	34.2 (0.4)			
Feeding state	35.0 (1.4) ^a		17.3 (0.7) ^a	a 100% E2
	37.0 (1.5) ^b	<u>17.7 (0.7)</u>	19.3 (0.8) ^b	b 50% M1 + 50% E2
	<u>39.2 (1.6)</u> ^c		<u>21.5 (0.9)</u> ^c	c 100% M1
Total energy	39.8 (1.6) ^a		22.1 (1.4) ^a	
	40.0 (1.6) ^b	17.7 (0.7)	22.3 (1.4) ^b	
	40.1 (1.6) ^c		22.4 (1.4) ^c	

$$\sigma_{m+g} = 40.1 (1.2) \text{ mb}$$

$$\sigma_{m+g} = \sigma_m + \sigma_g \text{ for 320 keV transition M1}$$

$$\text{isomeric ratio at } n_{\text{th}} \text{ is } \beta = 1.27 (0.09)$$

Phys. Rev. C 2002

$$\sigma_{\gamma}(E_{\text{th}}) = \underline{27.3} (0.8) \text{ mb} \quad 26.3 (1.2) \text{ mb (Blackmon et al.)}$$

$$\begin{aligned} \sigma_{\gamma}(E_{\text{th}}) &= \text{s-wave resonances} + \text{direct capture} \\ &= 8.3 (0.2) \text{ mb} + 14.0 \text{ mb} \\ &= \underline{22.3} \text{ mb} \end{aligned}$$

⇒ Experimental evidence of direct capture in ^{206}Pb

- Principle
 - Resonances for analysis of elemental composition
 - NRCA and NRT
- Data Analysis
 - Calibration approach
 - Methodological approach
- Applications
- NRA and PGAA
- Conclusions

- Neutron resonances appear at given energies, specific for each nuclide
- Nuclides can be identified and the elemental (and isotopic) composition can be deduced
- Applicable for almost all elements
- No sample preparation required
- Non - Destructive
- Negligible residual activation

(I)NAA

Intense thermal neutron flux (irradiation in core, i.e. BR1)

Gamma detector: gamma ray energy resolution \Rightarrow Ge-detectors

PGNAA

Intense neutron beam, (guided cold neutron beam Budapest, NIST)

Gamma detector: gamma ray energy resolution \Rightarrow Ge-detectors

NRA

Pulsed white neutron beam (LINAC)

Gamma/Neutron detector: good time resolution \Rightarrow scintillators

Pulsed Neutron Beam

White Neutron Energy Spectrum

TOF $\Leftrightarrow E_n$

$$E_n = \frac{1}{2} m_n v_n^2 = \frac{1}{2} m_n \left(\frac{L}{t} \right)^2$$

Good time resolution

High neutron flux

Intensity

$$\phi_n(E_n) \propto \frac{1}{L^2}$$

$L \uparrow \Rightarrow \phi_n \downarrow$

Resolution

$$R_n = \frac{\Delta E_n}{E_n} = 2 \sqrt{\frac{\Delta T_n}{T_n} + \frac{\Delta L}{L}}$$

$L \uparrow \Rightarrow R_n \downarrow$

Intensity

$$\phi_n(E_n) \propto \frac{1}{L^2}$$

$L \uparrow \Rightarrow \phi_n \downarrow$

Resolution

$$R_n = \frac{\Delta E_n}{E_n} = 2 \sqrt{\frac{\Delta T_n}{T_n} + \frac{\Delta L}{L}}$$

$L \uparrow \Rightarrow R_n \downarrow$

Detector

$$T = \frac{C_{in}}{C_{out}} \approx e^{-\sigma_{tot}}$$

no correction for efficiency

no normalisation required

but good collimation required

- All detected neutrons must have crossed the sample
- All neutrons scattered by the sample may not reach the detector

low sensitivity (exponential + potential scattering)

$$R_c = \varepsilon_c n_x \sigma_\gamma F \varphi S$$

- ε_c detection efficiency for capture event
- n_x number of nuclei per cm^2 for nuclide x
- σ_c capture cross section
- F** self-shielding factor
- S** Effective area
- φ neutron flux

$$F = \left(\frac{1 - e^{-n\sigma_t}}{n\sigma_t} \right)$$

More sensitive but the data analysis is more complicated

NRCA

Gamma Detectors - C_6D_6 , YAP

Good time resolution (1 ns)

Low neutron sensitivity

NRT

Neutron Detectors - Li glass

NE905

Good time resolution

PSND (developed at CCLRC)

Traditional approach Area analysis

$$R_c = \varepsilon_c n_x \sigma_\gamma F \varphi S$$

\Rightarrow

$$C_c = \varepsilon_c n_x A_\gamma F \varphi S$$

\Rightarrow only isolated resonances are used

Only valid for relatively weak resonances

neglect neutron scattering in the sample

Calibration

requires representative calibration samples to determine unknown and F

Limited in applications (no complex spectra, samples,...)

Limited use of information contained within the spectrum

However, **Very successful (e.g. Archeology, H. Postma)**

$$\frac{C_{r1,x}}{C_{r2,y}} = \frac{\varepsilon_{r1,x}}{\varepsilon_{r2,y}} \frac{F_{r1}}{F_{r2}} \frac{A_{\gamma,r1}}{A_{\gamma,r2}} \frac{\varphi_{r1}}{\varphi_{r2}} \frac{n_x}{n_y}$$

$$A_{\gamma,r} = 4.097 \times 10^6 \frac{g \Gamma_n \Gamma_\gamma}{E_r \Gamma} \text{ (b)}$$

- **φ neutron flux ($\varphi_{r1} / \varphi_{r2}$) (only shape required!!)**
 \Rightarrow Independent measurement by e.g. $^{10}\text{B}(n,\alpha)^7\text{Li}$
- **Resonance capture area ($A_{\gamma,r1}$ & $A_{\gamma,r2}$)**
 \Rightarrow From nuclear data libraries
- **ε detection efficiency for capture event ($\varepsilon_{r1} / \varepsilon_{r2}$)**
 \Rightarrow By calibration with standard samples (no correction for attenuation in sample)
- **Self - shielding factors (F_{r1} / F_{r2})**
 $\Rightarrow F = F(n, \sigma_{\text{tot}})$

$$F_r = \left(\frac{1 - e^{-n\sigma_t}}{n\sigma_t} \right)$$

$$n\sigma_t \ll 1 \Rightarrow F \cong 1$$

for main elements use weaker resonances
 for traces use stronger resonances

Looking at resonances of the same element ($n_x = n_y$)

$$\frac{C_{r1,x}}{C_{r2,x}} = \frac{\varepsilon_{r1,x}}{\varepsilon_{r2,x}} \frac{\varphi_{r1}}{\varphi_{r2}} \frac{A_{\gamma,r1}}{A_{\gamma,r2}} \frac{F_{r1}(n_x, \sigma_{t1})}{F_{r2}(n_x, \sigma_{t2})}$$

independent of n

$$\frac{C_{r1,x}}{C_{r2,x}} = \frac{1}{K} f(n_x, \sigma_{t,r1}, \sigma_{t,r2})$$

⇒ Thickness (n) from combination of resonances with different strength !!!

Sn

39 eV ^{117}Sn
 111 eV ^{116}Sn

Cu

230 eV ^{65}Cu
 650 eV ^{63}Cu
 994 eV ^{63}Cu
 1363 eV ^{65}Cu

NRCA requires capture yield, Y_c

Correction for the shape of the incoming neutron flux

Account for detection efficiency of the gamma event

(PHWT \Rightarrow NIM A 577 (2007) 626-640)

Advantages:

Resonance Shape Analysis (R-matrix) vs area analysis

Correction for self - shielding and multiple scattering

Resolution of TOF - spectrometer and Doppler broadening

The whole energy spectrum can be used to assess the nuclide abundance

Simultaneous fit of several data sets (both NRT and NRCA)

Easy to handle multi-elemental homogenous samples

G is an analytical model describing the observed capture yield:

$$Y_R = G(R, T, RP, F, \mu, S_x^*, n_x, S_y^*, n_y, \dots)$$

- R resolution of spectrometer
- T temperature (Doppler broad.)
- RP nuclear data to deduce σ_c, σ_t
- F self - shielding
- μ multiple scattering
- S_x^* binding energy nucleus x
- n_x atom density of nucleus x

$\Rightarrow n_x, n_y, \dots$: adjustable fitting parameters

Archaeology

PGAA (at Budapest) and NRCA (at GELINA) Accuracy for Cu in a bronze artefact about 1%

$\Rightarrow k_0$ and C_r relative to Cu

PGAA best for light elements

H, S, P, and K

NRCA best for heavy elements

As, Ag, Sb, Au and Pb

Both NRCA and PGAA are fully non-destructive methods for bulk analysis

The residual activation is negligible, especially for NRCA

PGAA is good for light elements, NRCA better for heavy elements

PGAA can be hampered by an unfavourable balance between the thermal capture cross sections of the elements
 \Rightarrow for NRCA we can always choose a region in the TOF-spectrum where the resonance of interest dominates

Pros:

- Multi elemental method
- High accuracy
- Low detection limits
- Most elements can be traced

Cons:

- Reactor (high flux) needed
- Activation, waiting time

Data needed:

- k_0 , g_w , I_r

OR

- Thermal cross sections
- Resonance Parameters
