I -Testing the WIMP Hypothesis with Indirect Searches in Gamma Rays

WIMPS
Fluxes
Spectra
DM Distribution

The WIMP hypothesis

- Dark Matter required by LambdaCDM Cosmology, Grav. Lensing, Cel. Dynamics
- **Beyond Standard Model physics** required
- “**natural**” candidates at the **weak scale** in several theories models (Super-symmetry, Universal Extra Dimensions, etc.), among others
- **WIMPs**, with EW properties, typical mass ~ 100 GeV and relic density thermally produced with cross-section $\langle\sigma v\rangle \sim 3 \times 10^{-26} \text{ cm}^3 \text{ s}^{-1}$

1

Indirect Dark Matter Fluxes

- DM particles annihilation or decay allow us to perform **Indirect Searches** in neutral and charged channels
- The neutral ones have (i) simpler propagation, (ii) **both spectral and spatial signatures**
- Expected flux typically factorized as Particle Physics factor and DM density distribution

$$\frac{d\Phi_\gamma}{dE_\gamma}(E_\gamma, \phi, \theta) = \underbrace{\frac{1}{4\pi} \frac{\langle \sigma_{ann} v \rangle}{2m_{WIMP}^2} \sum_f \frac{dN_\gamma^f}{dE_\gamma} B_f}_{\text{particle physics}} \times \underbrace{\int_{\Delta\Omega(\phi, \theta)} d\Omega' \int_{los} \rho^2(r(l, \phi')) dl(r, \phi')}_{\text{DM distribution}}$$

Here only annihilation considered

Gamma-ray Emission Spectra

- Choice of the particle physics model fixes final states and spectrum
- In general no simple power law spectra
- $b\bar{b}$ spectrum good proxy for hadronic channels (quarks and gauge bosons)
- Annihilation line “*smoking-gun*” signature, but $O(10^{-3} / 10^{-4})$ suppressed

Figures: Michael Kuhlen, Adv. in Astron. 2010

Dark Matter Distribution

- Large **DM halos** with sub-structures and a possible central density cusps
- Milky Way embedded in a DM halo
- The MW DM halo foreseen to have several associated sub-structures...
- ... and web of extra-galactic DM structures foreseen by n-body simulations

-15,000,000 -9,000,000

Gamma-ray emission in $\text{cm}^{-2} \text{s}^{-1}$ from an annihilating DM particle with a mass of 200 GeV. Only halos and subhalos at $z=0$ of the Millennium-II N-body simulation are considered.

From Fornasa et al, 2011 in prep.

Springel et al. NATURE 456, 44,
simulated gamma emission from annih. DM in the Milky
Way

14 18
 $\log S \text{ (M}_{\odot}^2 \text{kpc}^{-5} \text{s}^{-1})$

Electron anisotropies

Gamma Rays from Space

The Large Area Telescope

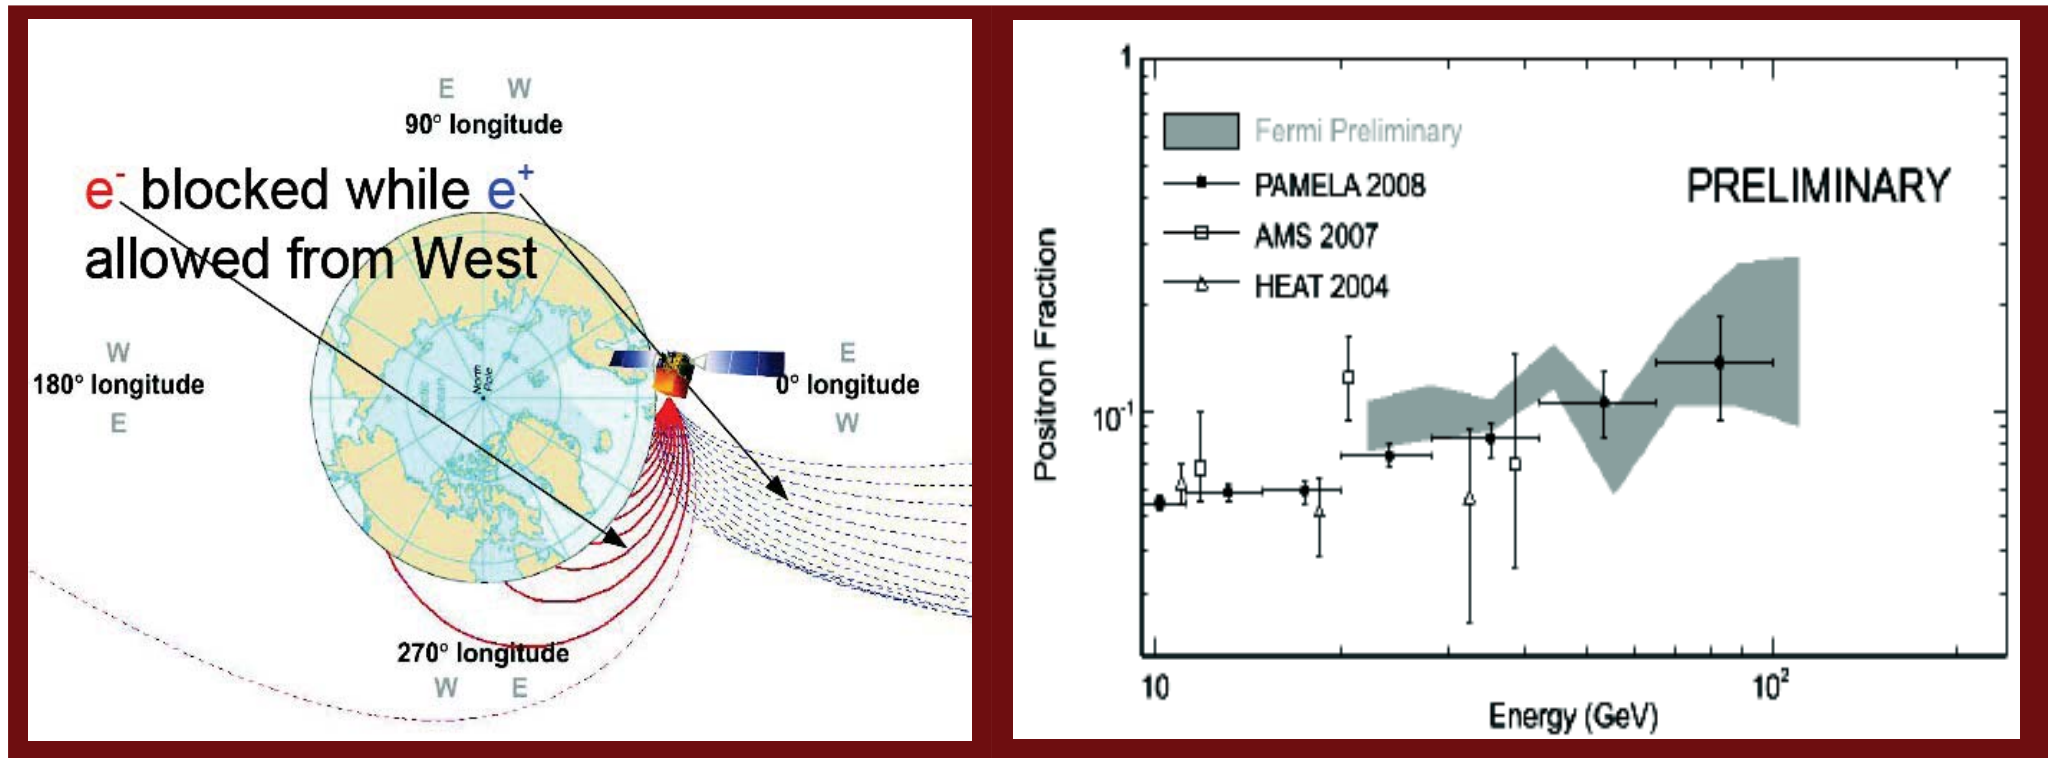

Charged Cosmic Rays electrons

- Spectrometers (PAMELA, AMS2) vs Calorimeters (ATIC, FERMI, IACTs)
- Statistics driven by ~size (acceptance), integrated livetime
- Inclusive spectrum $e^+ e^-$ spectrum is hard with no strong features (a TeV cutoff seen by HESS)
- CRE Anisotropies (Fermi) exclude single local astrophysical source (no dipole, but leave room for DM)

Charged Cosmic Rays (II)

- The Fermi-LAT measured the cosmic-ray positron and electron spectra separately, between 20 – 130 GeV, using the Earth's magnetic field as a charge discriminator
- The two independent methods of background subtraction, Fit-Based and MC-Based, produce consistent results
- The observed positron fraction is **consistent with** the one measured by **PAMELA** (e.g. rising and at odd with standard production of secondaries and anti-proton spectrum)

III – Current Fermi/LAT Results

Point Sources
Extended Sources
Diffuse Emission
(backup slides)
Unidentified Sources
The Galactic Halo

Dwarf Spheroidal Galaxies

- dSph are DM dominated systems (M/L up to 100-1000).
- Many dSphs closer than 100 kpc to the Galactic Centre.
- Cleanest known target
- Foreseen gamma-ray flux from DM dependent on the DM distribution
- U.L. on DM annihilation
- Previous results already close to cross-sections foreseen by some minimal super-symmetric extension of the Standard Model

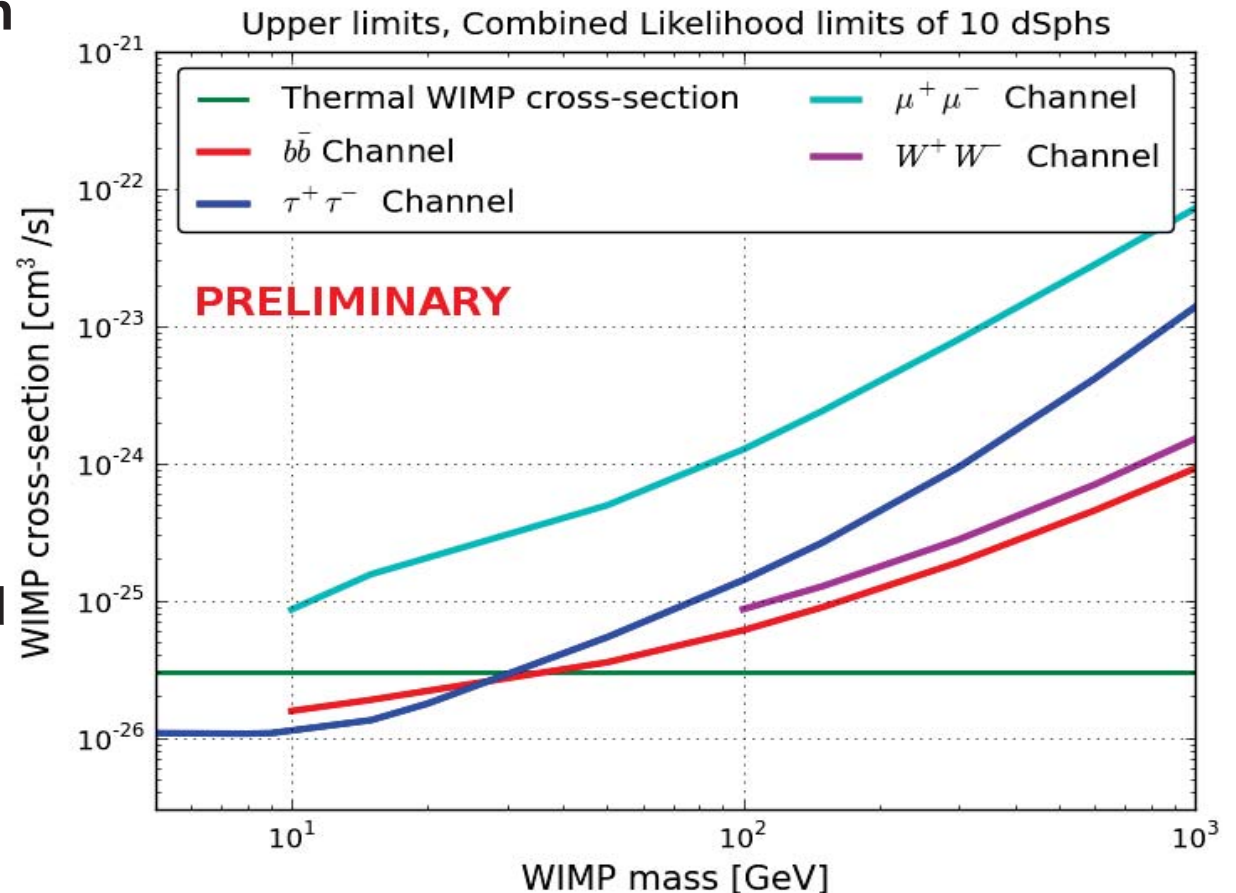

Dwarf Spheroidal Galaxies

- **Combined likelihood approach** within ST to derive combined upper limits for 10 dSphs.

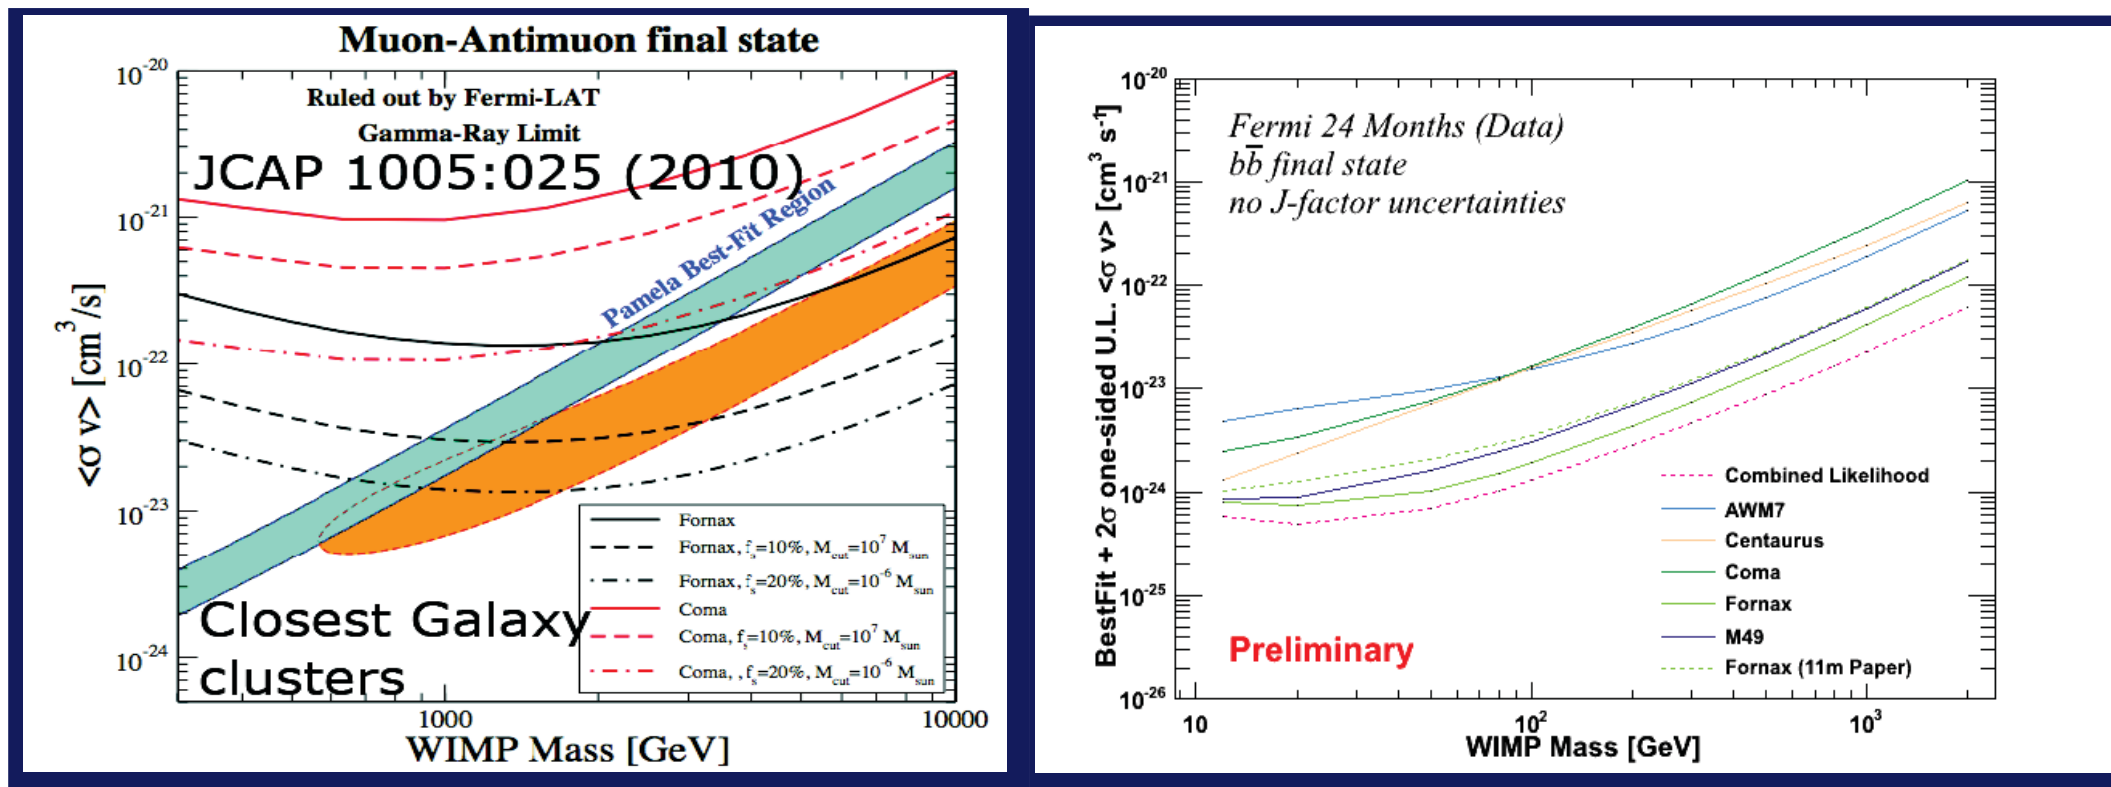

- The dSphs are first individually fitted and then added to the combined fit, where the DM is fitted as a common parameter. Backgrounds and surrounding sources are fitted individually within the combined fit.

- **J-factor uncertainties** included

- The limits cut into the thermal WIMP regime for: $b\bar{b}$ and $\tau^+\tau^-$ channels for $\text{WIMP} < 30 \text{ GeV}$

Galaxy Clusters

- U.L. on **DM annihilation or decay** (decay limits not shown here)
- Previous results **results disfavor lepto-philic DM** from CRE excesses
- New Combined likelihood analysis
- Energy between 200 MeV - 100 GeV (20 energy bins), P6v11 IRFs.
- All 1FGL sources within circle 15 degrees considered (fit of normalization parameter for those within 5 deg)
- Uncertainties in the J-factors NOT included

All-Sky Line Search

- Data extracted from a large fraction of the sky, the galactic plane used as control region
- No line feature detected from 7 to 200 GeV
- Spurious effects (CTBCORE) in the Pass 6v3 solved with the new Pass 7
- U.L. Constrain some scenarios (Higgs in space, some Gravitino decay, npn thermal WIMPs)

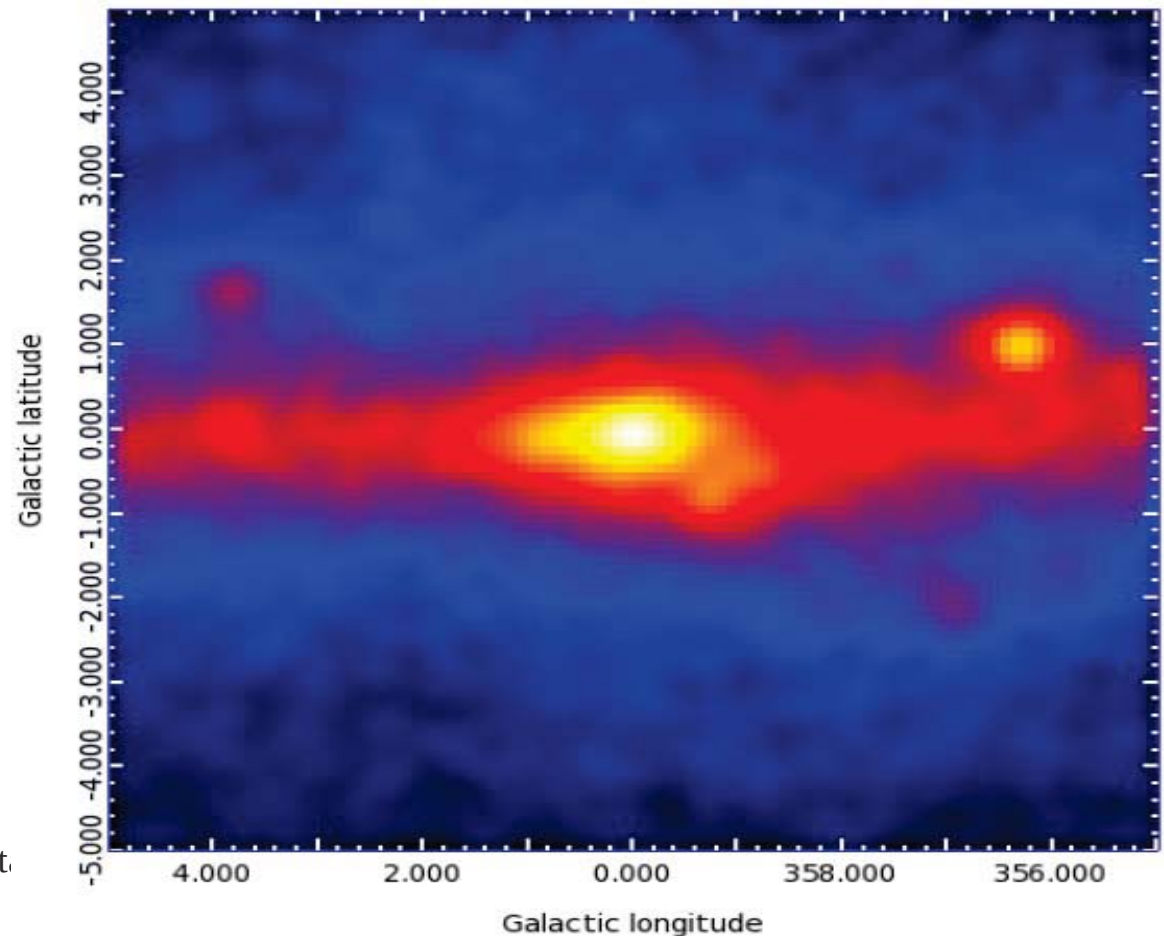

The Inner Galaxy

- The Milky Way centre *might* be (according to N-body simulations) the brightest dark matter gamma-ray source
- The region hosts a large number of sources (and possibly many unresolved ones)
- Diffuse gamma emission from interaction of cosmic rays with the interstellar gas and radiation fields: **(i) Inverse Compton**; **(ii) Bremsstrahlung**; **(iii) neutral pions decay**
- Diffuse emission coming from the from: (1) Outer galaxy, (2) True inner galaxy; (3) possible unresolved sources

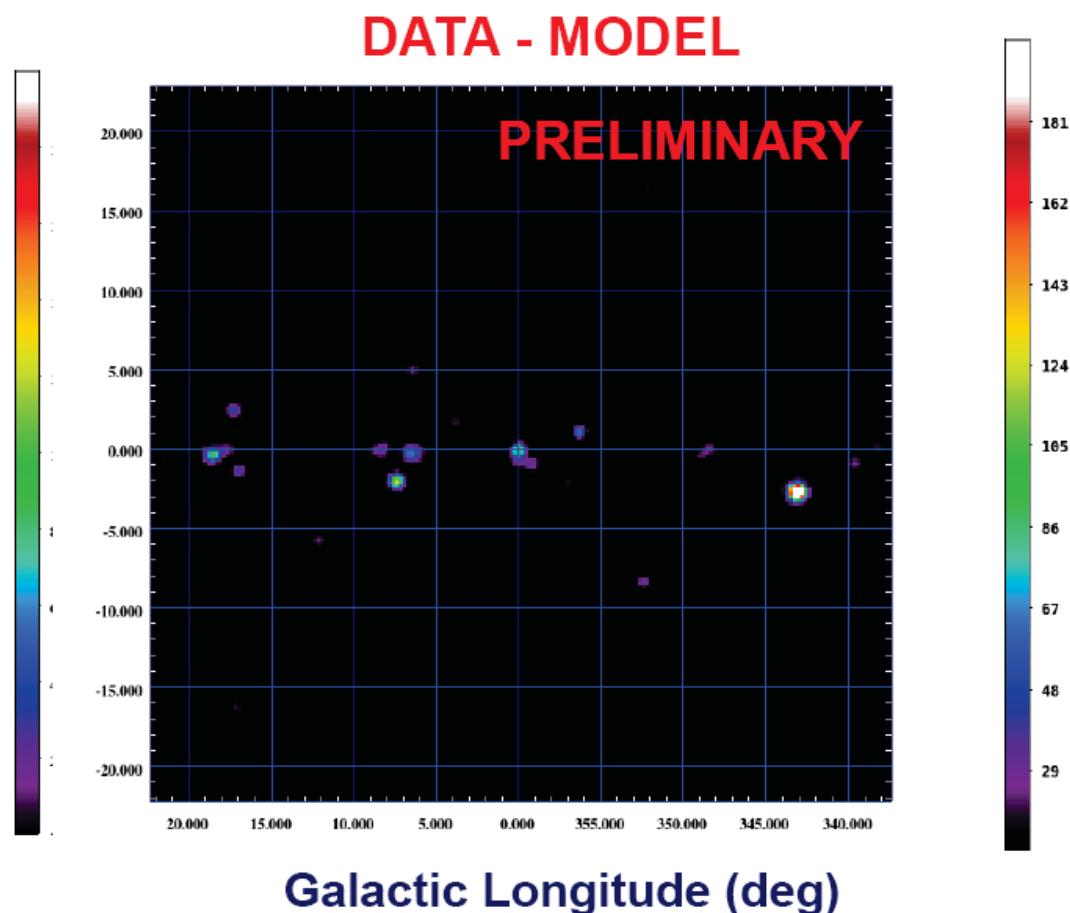

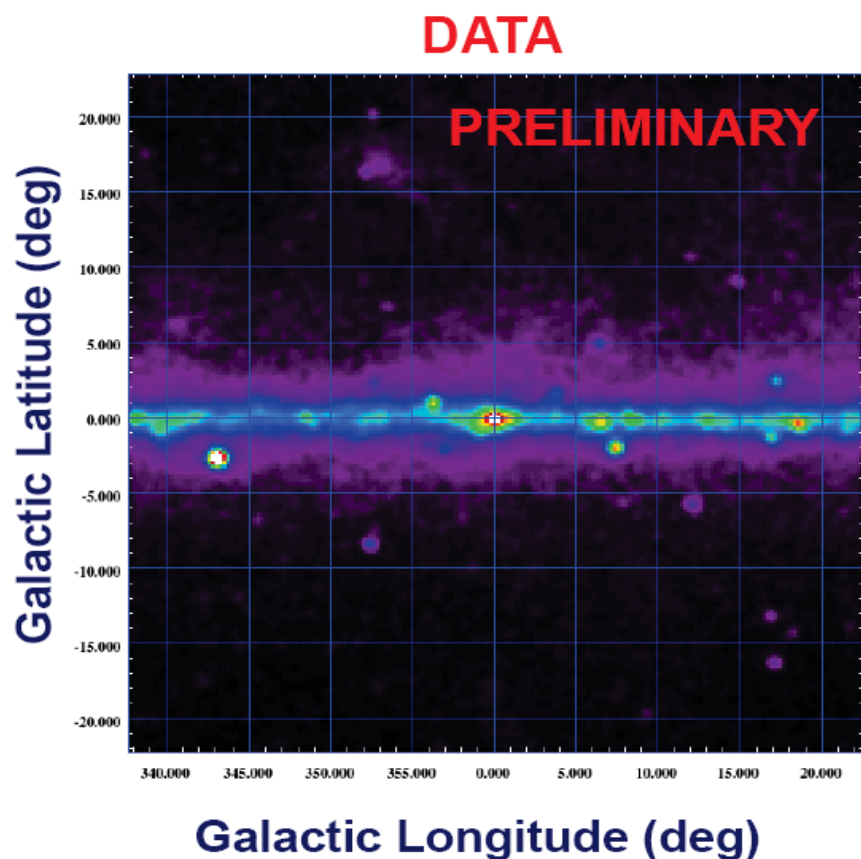

Vincenzo Vit

The Inner Galaxy (II)

- Currently work in progress for modelling the the diffuse emission in the Inner Galaxy region (45X45deg) with physically-motivated model based on GALPROP
- In the residual emission (data – diffuse model) maps the bright known sources are visible
- Work in progress to characterise the low-level residual structures and point sources
- Possible to find combination of diffuse model + sources that describe the innermost region with relatively flat residuals
- Forthcoming paper(s) will describe the method and results in detail

III – Anisotropies in the Diffuse Emission

Angular Power Spectrum

The Analysis Results

(backup slides)

Measurement of the IGRB

Milky Way Lobes/Bubbles

Intensity Maps

APS from Sources

Angular Power Spectrum (APS)

$$I(\psi) = \sum_{\ell, m} a_{\ell m} Y_{\ell m}(\psi)$$

L.Knox
1995PhRvD..52.4307K

$$C_{\ell} = \langle |a_{\ell m}|^2 \rangle$$

$$\delta C_{\ell}^s = \sqrt{\frac{2}{(2\ell + 1) \Delta\ell f_{\text{sky}}}} \left(C_{\ell}^s + \frac{C_N}{W_{\ell}^2} \right)$$

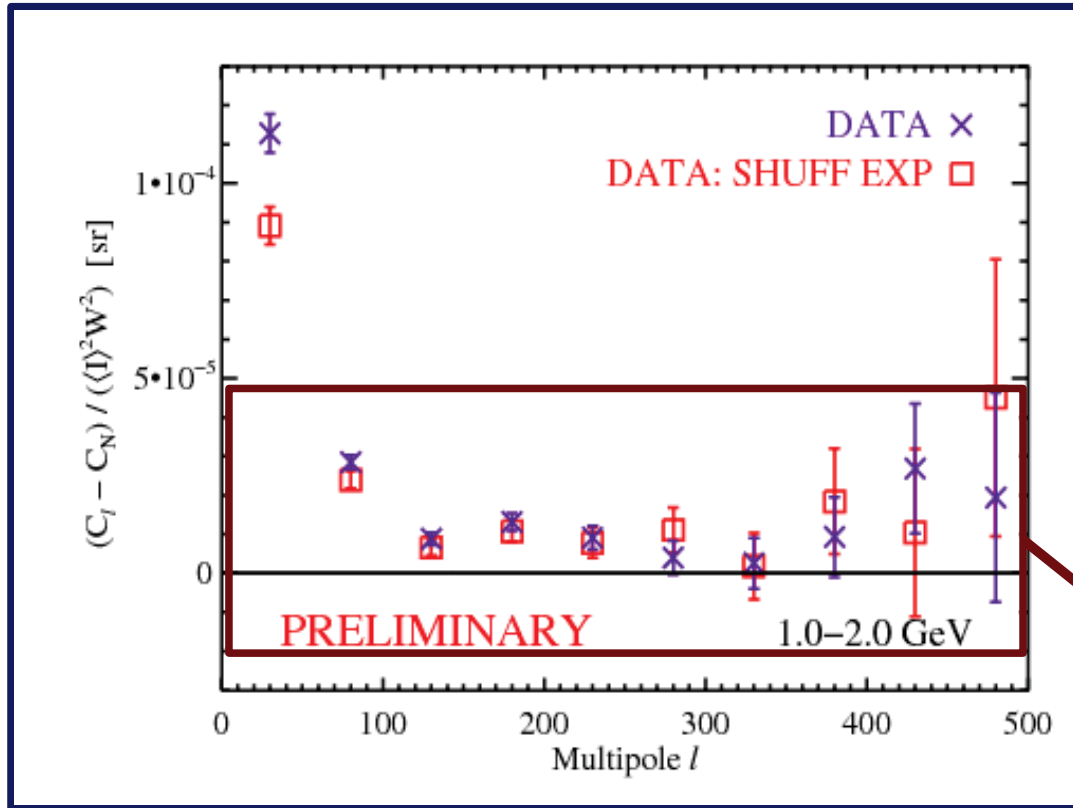

- A diffuse background can be built by the sum of a **large number of un-resolved faint sources** (possibly **DM Halos and sub-structures**, for example)
- Fluctuations from source populations can be identified, if different from the Poisson noise ones;
- the energy-dependence of the anisotropy can reveal/constrain multiple population
- Diffuse emission fluctuations can be studied with spher. harmonics expansions
- **C_{ℓ} = intensity APS** : indicates dimensionful amplitude of anisotropy
- **$C_{\ell} / \langle I \rangle^2$ = fluctuation APS**: dimensionless, independent of intensity normalization, with **f_{sky}** = un-masked fraction of the sky, **W_{ℓ}** =window function; **$\Delta\ell$** =multipole bin, **C_n** = noise angular power;

Studying Anisotropy in the IRGB

- **Fermi/LAT** all-sky observations from the first 22 months of operation
- The APS of the data are obtained from binned **Intensity maps**;
- **HEALPix** (Gorski et al 2005) used;
- Known sources and Galactic diff. em. minimized with **masking**;
- In the main analysis branch gtools were used for the exposure maps calc.
- An independent method (**Shuffling**) used to cross-check the exposure calculation effects;
- APS of real data and detailed **all-sky simulations** have been obtained and compared;
- A **Foreground Cleaning** has been used to estimate the possible effects of residual Galactic diffuse emission

APS of the Data

- For multipoles < 100 excess of angular power likely coming from the Galactic diffuse background
- For multipoles > 150 an excess of angular power is detected

measurement uncertainties:
indicate 1-sigma statistical
uncertainty, systematic
uncertainty not included

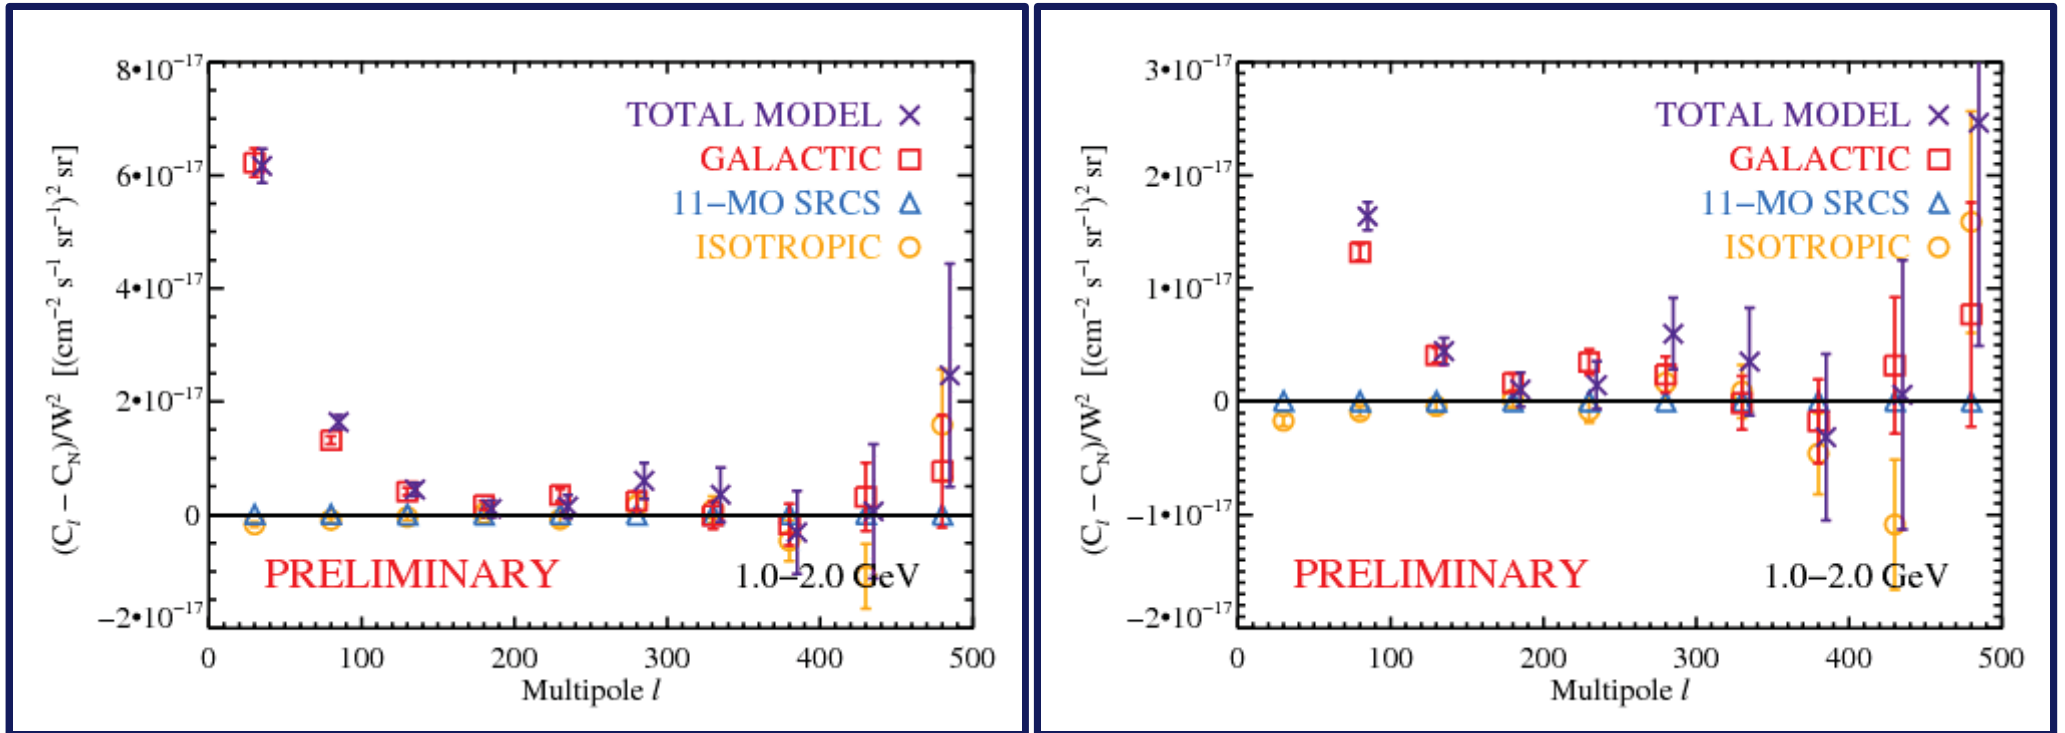

Simulated Sky Comparison (i)

- All-sky simulations APS compared to real data ones
- Simulated: 1FGL sources (1451), Galactic diffuse emission (the standard gll_iem_v02.fit at 0.5deg resolution and a version at 0.125deg resolution), Isotropic diffuse emission;
- Other energy bins in backup slides

Simulated Sky Comparison(ii)

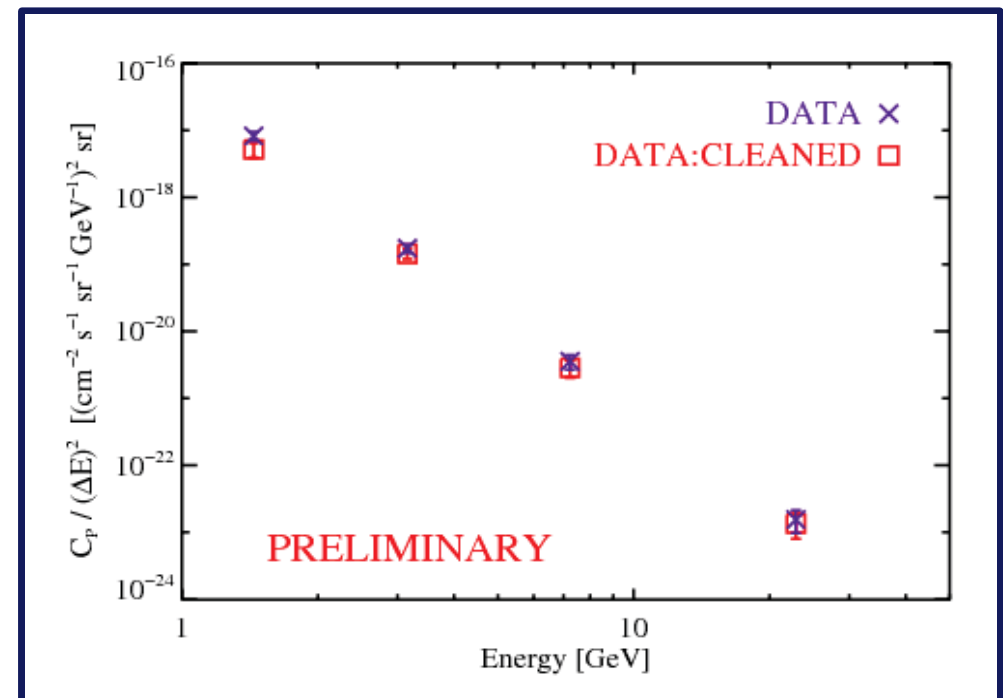

- Galactic diff. Model shows low multipole ($l < 100$) excess
- Isotropic diffuse and sources follow expected behaviour
- Other energy bins in backup slides

Angular Power in the Data

E_{\min} [GeV]	E_{\max} [GeV]	C_P [(cm ⁻² s ⁻¹ sr ⁻¹) ² sr]	Significance	$C_P / \langle I \rangle^2$ [10 ⁻⁶ sr]
1.04	1.99	$7.39 \pm 1.14 \times 10^{-18}$	6.5σ	10.2 ± 1.6
1.99	5.00	$1.57 \pm 0.22 \times 10^{-18}$	7.2σ	8.35 ± 1.17
5.00	10.4	$1.06 \pm 0.26 \times 10^{-19}$	4.1σ	9.83 ± 2.42
10.4	50.0	$2.44 \pm 0.92 \times 10^{-20}$	2.7σ	8.00 ± 3.37

- Angular power detect with high significance up to 10GeV, and with a lower one at larger energies;
- Fluctuation angular power of 10⁻⁵ sr in the range predicted for astrophysical source classes and some DM scenarios

Energy Dependence of APS

- Fluctuation anisotropy energy spectrum consistent with no energy dependence and contributed by one or more source classes providing same fractional intensity contribution at all energies
- Intensity anisotropy energy spectrum consistent with one or more source classes with photon index -2.40 ± 0.07 (such as FSRQs and BL Lacs)

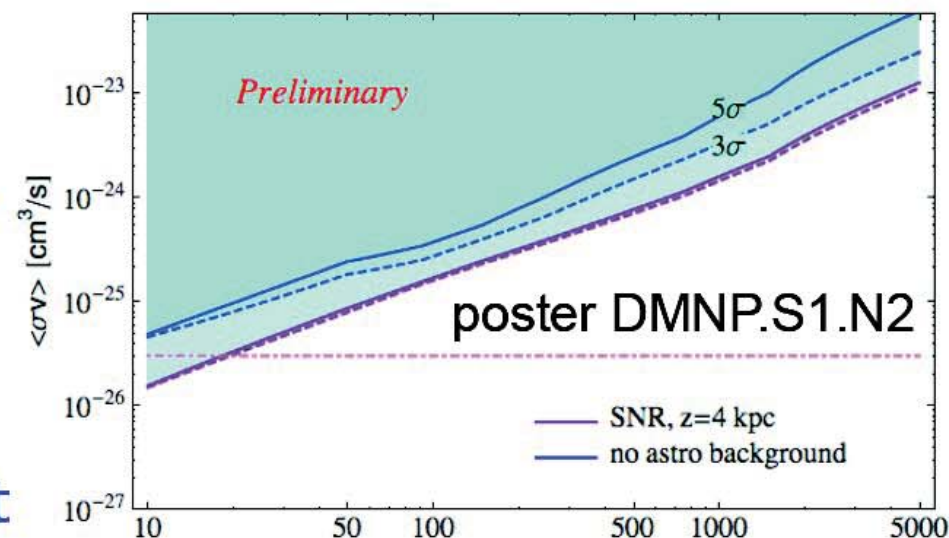

V – Conclusions

- Fermi and Pamela provide coherent observational picture
 - Fermi and IACT complementary in energy range
 - Neutrino initial results important for a comprehensive observational program
-
- Only upper limits so-far
 - Point sources cleanest target
 - Fermi limits from dwarfs scratching WIMP benchmark thermal cross section at ~ 10 GeV
 - All sky (EGB, line, anisotropies) accessible to Fermi only
 - Extended regions (halo, Inner Galaxy) promising but hard
 - Diffuse emission is the maximal uncertainty, needed input from Fermi and other missions to improve modeling
-
- Wealth of results from Indirect Dark Matter searches
 - Gamma-ray results disfavor lepto-philic DM for CRE excesses
 - Hints from direct or accelerator searches reduce models phase space for cross-checks

Backup Slides

- ❑ Exploits both spectral and spatial information
 - Data binned in E and angle
- ❑ Large residuals in the fit favor a DM component
 - scan model parameters of diffuse emission that affect more significantly DM limits
 - Compute limits assuming all diffuse emission is DM
- ❑ Simultaneously fit CR and gamma-ray data scanning full phase space of CR models

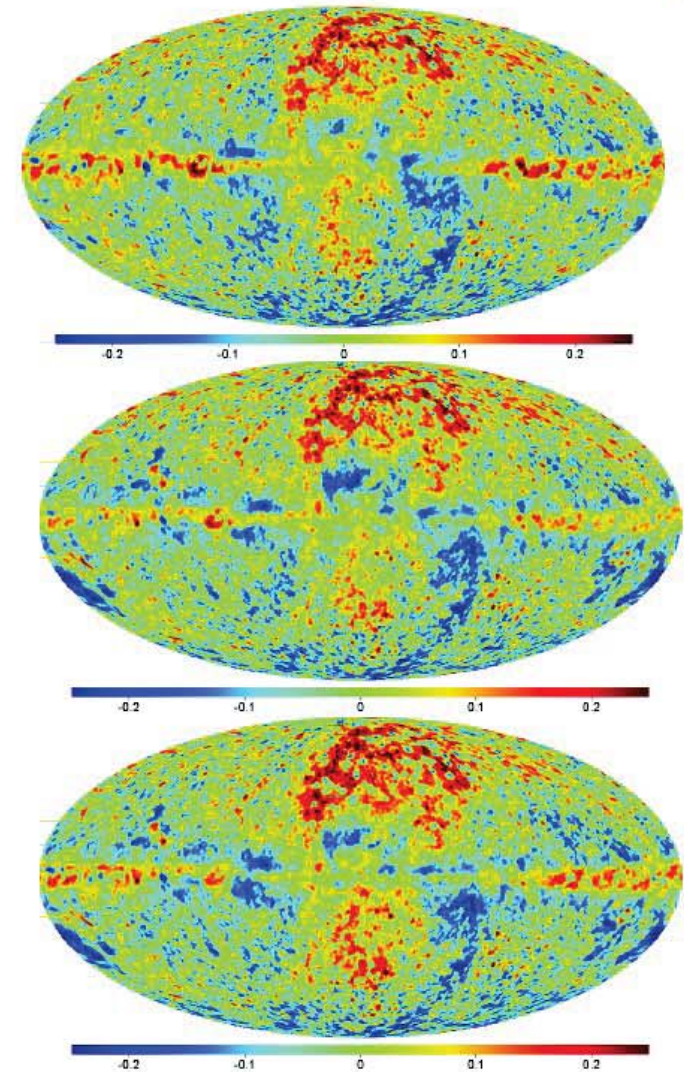

NFW, $b\bar{b}$

Challenge with Halo Analysis

- ❑ Residual maps from a selection of GALPROP models show considerable large scale structures
 - Fermi lobes, Loop I, bubbles ... see talk by JM Casandjian

Data Intensity Maps

Counts Map (1-2GeV)

Masked Counts Map

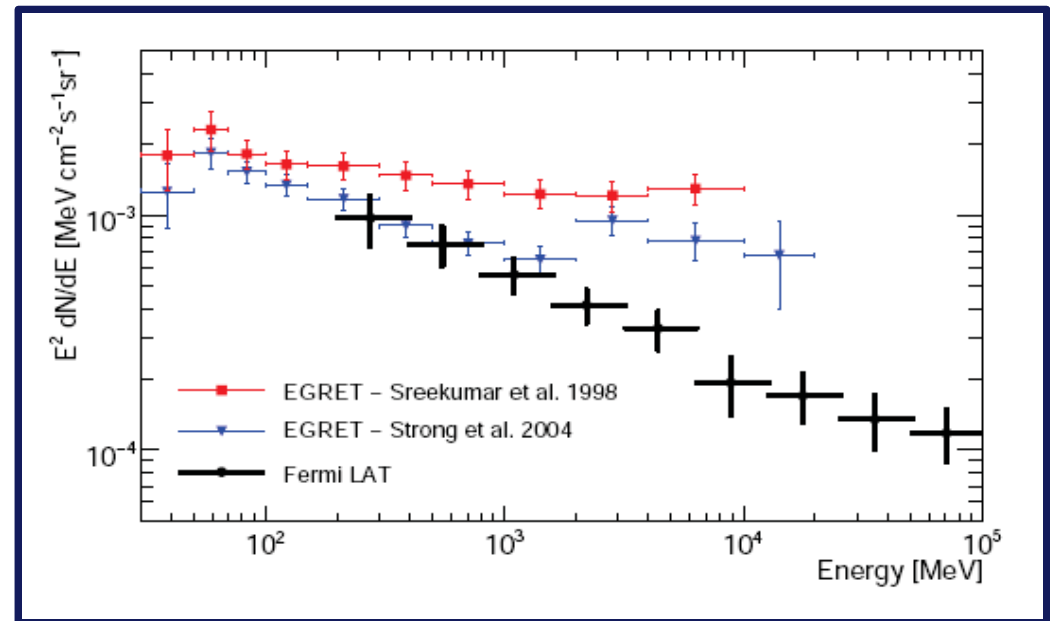

Sources Masking

Galactic Plane Masking

- **22 months** of data, diffuse class events
- energy from **1 to 50 GeV**, **4 energy bins** for APS calculation
- **Masking** of 11-month catalog sources (2deg radius) and $|b| < 30$ deg diffuse emission
- front- and back-converting events: processed separately through angular power spectrum calculation, then results are combined by weighted average

Measurement of the IGRB

- Galactic Diffuse Emission component
- Extra-Galactic Diffuse Emission component, with photon index -2.40 ± 0.05 and $I(E > 0.1 \text{ GeV}) = (1.03 \pm 0.17) \times 10^{-5} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$
- Residual Charged Cosmic Rays component
- Guaranteed contributions to IGRB: blazars, star forming galaxies, milli-second pulsars
- Possible contributions: Dark matter structures, etc

APS from Sources

- The Poisson angular power arises from un-clustered point sources and takes the same value at all multipoles
- The APS of many gamma-ray source pop. are dominated by the Poisson components for multipoles $l > 10$
- The measured one is $\sim 1e-5$ sr, then within the range predicted for some astrophysical source classes and some dark matter scenarios
- Other source populations APS in the backup

predicted fluctuation angular power $C_\ell/\langle I \rangle^2$ [sr] at $l = 100$ for a single source class (LARGE UNCERTAINTIES):

- blazars: $\sim 1e-4$
- starforming galaxies: $\sim 1e-7$
- dark matter: $\sim 1e-4$ to ~ 0.1
- MSPs: $\sim 1e-2$

Fermi updates on sources

- ❑ No DM satellites found in 1 year of data when requiring
 - Spectrum inconsistent with conventional power law
 - source extension (almost all pulsars pass simple spectral tests)

Search for CRE anisotropy

- The arrival directions of events from the whole sky were searched for anisotropies in Galactic coordinates
 - Healpix pixelization scheme (12288 pixels, $\approx 3\text{deg}^2$) used for the skymaps

Significance skymaps

A pre-trials significance map produced by a bin to bin comparison of the no-CRE-anisotropy to the actual skymap:

- Integration radius 10° , 30° , 60° and 90° and Energy $>60\text{GeV}$
- Because of the large number of trials (from ≈ 100 trials at 90° up to ≈ 5000 at 10° integration angular radius) all the observed fluctuations are *post-trials insignificant*
