Dye desorption steps:

Framework: What is TDDFT all about?

1964: Hohenberg and Kohn: Density Functional Theory (DFT)

work in terms of electron density (instead of many-particle wavefunctions)

DFT is a **ground state** theory

1984: Runge and Gross: **Time-Dependent** Density Functional Theory (TDDFT)

$$\text{Given } |\Psi(t=0)\rangle : V(\mathbf{r}, t) \Leftrightarrow n(\mathbf{r}, t)$$

like DFT, TDDFT is **formally exact**

Recall: Basic ground-state DFT

For practical calculations: Kohn-Sham framework

$$n_{\sigma}(\mathbf{r}) = \sum_i^{N_{\sigma}} |\phi_{i\sigma}(\mathbf{r})|^2$$

The density is written in terms of Kohn-Sham orbitals which satisfy

$$\left[-\frac{\nabla^2}{2} + v_{\sigma}^{KS}[n_{\uparrow}, n_{\downarrow}](\mathbf{r}) \right] \phi_{i\sigma}(\mathbf{r}) = \epsilon_{i\sigma} \phi_{i\sigma}(\mathbf{r})$$

$$\begin{aligned} F[n_{\uparrow}, n_{\downarrow}] &= T_s[n_{\uparrow}, n_{\downarrow}] + E_{Hartree} + E_{xc}[n_{\uparrow}, n_{\downarrow}] \\ E_{Hartree} &= \frac{1}{2} \int d^3r \int d^3r' \frac{n(\mathbf{r}) n(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} \\ E_{xc}^{LDA} &= \int d^3r n(\mathbf{r}) \epsilon_{xc}^{unif}(n_{\uparrow}(\mathbf{r}), n_{\downarrow}(\mathbf{r})) \end{aligned}$$

The Runge-Gross Theorem

Generalizing the HK theorem to time-dependent systems

There exists a one-to-one correspondence between the external $v(\mathbf{r},t)$ and the electron density $n(\mathbf{r},t)$, for systems evolving from a fixed many-body state.

Proof:

$$\begin{aligned} |\Psi(t_0)\rangle &= |\Psi'(t_0)\rangle \equiv |\Psi_0\rangle \\ n(\mathbf{r}, t_0) &= n'(\mathbf{r}, t_0) \equiv n^0(\mathbf{r}) \\ \mathbf{j}(\mathbf{r}, t_0) &= \mathbf{j}'(\mathbf{r}, t_0) \equiv \mathbf{j}^0(\mathbf{r}) \end{aligned}$$

Step 1: Different potentials v and v' yield different current densities \mathbf{j} and \mathbf{j}'

Step 2: Different current densities \mathbf{j} and \mathbf{j}' yield different densities n and n'

$$v(\mathbf{r}, t) \neq v'(\mathbf{r}, t) + c(t) \quad \Rightarrow \quad n(\mathbf{r}, t) \neq n'(\mathbf{r}, t)$$

Using TDDFT in practice

Finding an equivalent of the Kohn-Sham formalism

$$i\frac{\partial}{\partial t}\varphi_{i\sigma}(\mathbf{r},t) = \hat{H}_{\sigma}^{\text{KS}}(\mathbf{r},t)\varphi_{i\sigma}(\mathbf{r},t)$$

With a time-dependent Hamiltonian:

$$\hat{H}_{\sigma}^{\text{KS}}(\mathbf{r},t) = -\frac{\nabla^2}{2} + v_{\sigma}^{\text{KS}}[n_{\uparrow},n_{\downarrow}](\mathbf{r},t)$$

Density and potentials are now defined like:

$$n_{\sigma}(\mathbf{r},t) = \sum_i^{N_{\sigma}} |\varphi_{i\sigma}(\mathbf{r},t)|^2$$

$$v_{\sigma}^{\text{KS}}[n_{\uparrow},n_{\downarrow}](\mathbf{r},t) = v_{\sigma}(\mathbf{r},t) + \int d^3r' \frac{n(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} + v_{\sigma}^{\text{xc}}[n_{\uparrow},n_{\downarrow}](\mathbf{r},t)$$

Which functional to use ?

The easiest and probably most widely used functional is the
Adiabatic Local Density Approximation (ALDA)

$$v_{\sigma}^{\text{xc ALDA}}(\mathbf{r}, t) = \frac{\partial}{\partial n_{\sigma}} \left[n \varepsilon_{\text{xc}}^{\text{unif}}(n_{\uparrow}, n_{\downarrow}) \right] \Big|_{n_{\alpha} = n_{\alpha}(\mathbf{r}, t)}$$

TDDFT in real time:

(1996:Bertsch; 2001: Octopus code)

- Consider a general time-dependent perturbation:

$$V_{pert}(\mathbf{r}, t)$$

- Obtain orbitals, charge density, and potentials by solving the Schrödinger equation explicitly in **real time**:

$$\psi_j(t + \Delta) = \exp \left(-iH(t + \frac{\Delta}{2})\Delta \right) \psi_j(t)$$

(*Nonlinear* TD Schrödinger equation)

- Can be used for *linear response* calculations, or for general TD *non-linear* problems.

A first application: Photochemistry

- Recent experimental progress made it possible to produce ultra-short intense laser pulses (few fs)
- This allows one to probe bond breaking/formation, charge transfer, etc. on the relevant time scales
- Nonlinear real-time TDDFT calculations can be a valuable tool to understand the physics of this kind of probe.
- Visualizing chemical bonds: Electron localization function

Nonlinear optical response

- Electron localization function:

$$ELF(\mathbf{r}, t) = \frac{1}{1 + [D_\sigma(\mathbf{r}, t)/D_\sigma^0(\mathbf{r}, t)]^2}$$

$$D_\sigma(\mathbf{r}, t) = \tau_\sigma(\mathbf{r}, t) - \frac{1}{4} \frac{[\nabla n_\sigma(\mathbf{r}, t)]^2}{n_\sigma(\mathbf{r}, t)} - \frac{j_\sigma^2(\mathbf{r}, t)}{n_\sigma(\mathbf{r}, t)}$$

Example: Ethyne C_2H_2

Example: Ethyne C_2H_2

How can we calculate optical spectra?

Consider a perturbation δV applied to the ground-state system:

$$\delta n(r, t) = \int d^3 r' dt' \chi(r, r'; t - t') \delta V(r', t')$$

The induced dipole is given by the induced charge density:

$$d(t) = \int d^3 r \delta n(r, t) \hat{r}$$

Consider the perturbation due to an electric field:

$$\delta V(r, t) = -e E_{ext}(t) \cdot \hat{r}$$

How can we calculate optical spectra?

The dipole susceptibility is then given by:

$$d(t) = \int dt' \alpha(t - t') E_{ext}(t')$$

The experimentally measured strength function S is related to the Fourier transform of α :

$$S(\omega) = \frac{2m}{\pi e^2 \hbar} \omega \operatorname{Im} \alpha(\omega)$$

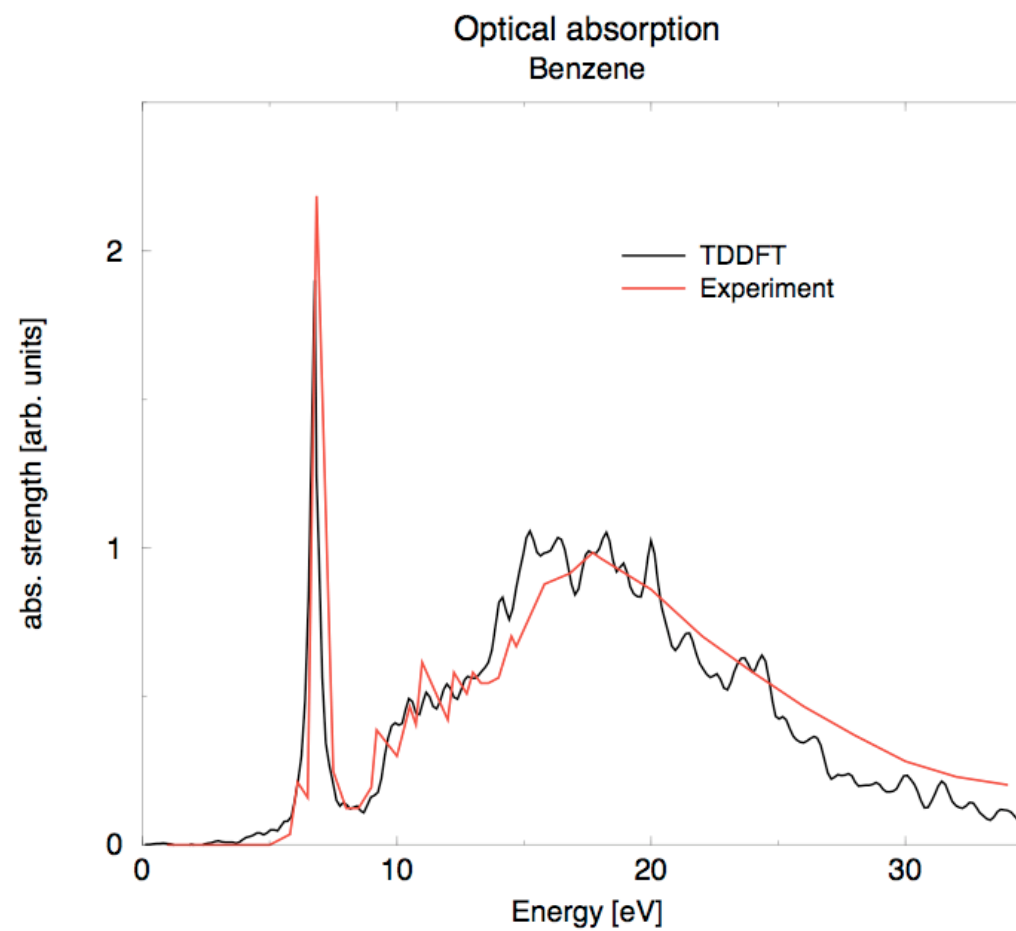

In practice: We take an E-field pulse $E_{ext} = E_0 \delta(t)$, calculate $d(t)$, and obtain the spectrum $S(\omega)$ by calculating

$$d(\omega) = \int_0^\infty dt e^{i\omega t - \delta t} d(t)$$

A typical dipole-function $d(t)$...

... and the resulting spectrum

Linear response formalism in TDDFT:

- Calculate the system's ground state using DFT

- Consider a monochromatic perturbation:

$$V_{pert}(\mathbf{r}, t) = V_0(\mathbf{r}) (\exp(i\omega t) + \exp(-i\omega t))$$

- Linear response: assume the time-dependent response:

$$\psi_j(t) = e^{-i\epsilon_j t} (\psi_j^0 + \delta\psi_j^+ e^{i\omega t} + \delta\psi_j^- e^{-i\omega t})$$

$$\delta n(\mathbf{r}, t) = \delta n^+(\mathbf{r}) e^{i\omega t} + \delta n^-(\mathbf{r}) e^{-i\omega t}$$

$$\delta V(\mathbf{r}, t) = V_{pert}(\mathbf{r}, t) + \delta V_{SCF}^+(\mathbf{r}) e^{i\omega t} + \delta V_{SCF}^-(\mathbf{r}) e^{-i\omega t}$$

- Put these expressions into the TD Schrödinger equation

Linear response formalism in TDDFT:

$$\begin{aligned}\omega \delta \psi_v^+(\mathbf{r}) &= \left(H_{KS}^0 - \epsilon_v^0 \right) \delta \psi_v^+ + \hat{P}_{\mathbf{c}} \left(\delta V_{SCF}^+(\mathbf{r}) + V_{pert}(\mathbf{r}) \right) \psi_v^0(\mathbf{r}) \\ -\omega \delta \psi_v^-(\mathbf{r}) &= \left(H_{KS}^0 - \epsilon_v^0 \right) \delta \psi_v^- + \hat{P}_{\mathbf{c}} \left(\delta V_{SCF}^-(\mathbf{r}) + V_{pert}(\mathbf{r}) \right) \psi_v^0(\mathbf{r})\end{aligned}$$

Now define the following linear combinations:

$$\begin{aligned}x_v(\mathbf{r}) &= \frac{1}{2} (\delta \psi_v^+(\mathbf{r}) + \delta \psi_v^-(\mathbf{r})) \\ y_v(\mathbf{r}) &= \frac{1}{2} (\delta \psi_v^+(\mathbf{r}) - \delta \psi_v^-(\mathbf{r}))\end{aligned}$$

$$(\omega - \mathcal{L}) |\boldsymbol{x}, \boldsymbol{y}\rangle = |\mathbf{0}, \boldsymbol{v}\rangle \qquad \mathcal{L} = \begin{pmatrix} 0 & D \\ K & 0 \end{pmatrix}$$

With the following definitions:

$$\begin{aligned} D |\boldsymbol{x}\rangle &= \left\{ (H_{KS}^0 - \epsilon_i) \boldsymbol{x}_i(\boldsymbol{r}) \right\} \\ K |\boldsymbol{x}\rangle &= \left\{ (H_{KS}^0 - \epsilon_i) \boldsymbol{x}_i(\boldsymbol{r}) + \psi_i^0(\boldsymbol{r}) \sum_j \int d\boldsymbol{r}' f_{Hxc}(\boldsymbol{r}, \boldsymbol{r}') \psi_{i'}^0(\boldsymbol{r}') \boldsymbol{x}_{i'}(\boldsymbol{r}') \right\} \end{aligned}$$

$$\begin{pmatrix} 0 & D \\ K & 0 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \omega \begin{pmatrix} x \\ y \end{pmatrix}$$

Linear response TD-DFT essentially means solving a **non-hermitean** eigenvalue equation of dimension $2 N_v \times N_c$.

Standard way to proceed (Casida's equations):

- Solve the time-independent problem to **completely diagonalize** the ground-state Hamiltonian.

[Some computer time can be saved by limiting the diagonalization to the lower part of the spectrum]

- Obtain as many eigenstates/frequencies of the TD-DFT problem as needed (or as possible).

[Some computer time can be saved by transforming the non-hermitean problem to a hermitean one (e.g. Tamm-Dancoff approx.)]

Advantages:

One obtains not only the frequency (and oscillator strength), but the full eigenvector of each elementary excitation.

[Info can be used for spectroscopic assignments, to calculate forces, etc]

Disadvantages:

One obtains not only the frequency (and oscillator strength), but the full eigenvector of each elementary excitation.

[Info is often not needed, all the information is immediately destroyed after computation]

Computationally extremely demanding (large matrices to be diagonalized)

Time-dependent density functional perturbation theory (TDDFPT)

Remember: The photoabsorption is linked to the dipole polarizability $\alpha(\omega)$

$$d(t) = \int dt' \alpha(t - t') \mathcal{E}(t')$$

If we choose $\mathcal{E}(t') = \mathcal{E}_0 \delta(t')$, then knowing $d(t)$ gives us $\alpha(t)$ and thus $\alpha(\omega)$.

Therefore, we need a way to calculate the observable $d(t)$, given the electric field perturbation $\mathcal{E}_0 \delta(t)$.

Consider an observable A:

$$A(t) = \sum_i \left(\langle \delta\psi_i(t) | \hat{A} | \psi_i^0 \rangle + \langle \psi_i^0 | \hat{A} | \delta\psi_i(t) \rangle \right)$$

Its Fourier transform is:

$$\begin{aligned} \tilde{A}(\omega) &= \sum_i \left(\langle \psi_i^0 | \hat{A} | \delta\psi_i^-(\omega) \rangle + \langle \psi_i^0 | \hat{A} | \delta\psi_i^+(\omega) \rangle \right) \\ &= 2 \sum_i \langle \psi_i^0 | \hat{A} | x_i(\omega) \rangle \\ &= 2 \langle a, 0 | x, y \rangle \end{aligned}$$

$$\begin{aligned}
\tilde{A}(\omega) &= \sum_i \left(\langle \psi_i^0 | \hat{A} | \delta\psi_i^-(\omega) \rangle + \langle \psi_i^0 | \hat{A} | \delta\psi_i^+(\omega) \rangle \right) \\
&= 2 \sum_i \langle \psi_i^0 | \hat{A} | x_i(\omega) \rangle \\
&= 2 \langle \mathbf{a}, \mathbf{0} | \mathbf{x}, \mathbf{y} \rangle
\end{aligned}$$

Recall: $(\omega - \mathcal{L}) | \mathbf{x}, \mathbf{y} \rangle = | \mathbf{0}, \mathbf{v} \rangle$

Therefore:

$$\tilde{A}(\omega) = 2 \langle \mathbf{a}, \mathbf{0} | (\omega - \mathcal{L})^{-1} | \mathbf{0}, \mathbf{v} \rangle$$

Thus in order to calculate the spectrum, we need to calculate one given matrix element of $(\omega - \mathcal{L})^{-1}$.

In order to understand the method, look at the hermitean problem:

$$\langle v | (\omega - H)^{-1} | v \rangle$$

Build a Lanczos recursion chain:

$$\phi_{-1} = 0$$

$$\phi_0 = |v\rangle$$

$$b_{n+1}\phi_{n+1} = (H - a_n)\phi_n - b_n\phi_{n-1}$$

$$\langle \phi_{n+1} | \phi_{n+1} \rangle = 1$$

$$a_n = \langle \phi_n | H | \phi_n \rangle$$

$$H = \begin{pmatrix} a_0 & b_1 & 0 & \dots & 0 \\ b_1 & a_1 & b_2 & 0 & \vdots \\ 0 & b_2 & a_2 & \ddots & 0 \\ \vdots & 0 & \ddots & \ddots & b_n \\ 0 & \dots & 0 & b_n & a_n \end{pmatrix}$$

$$H = \begin{pmatrix} a_0 & b_1 & 0 & \dots & 0 \\ b_1 & a_1 & b_2 & 0 & \vdots \\ 0 & b_2 & a_2 & \ddots & 0 \\ \vdots & 0 & \ddots & \ddots & b_n \\ 0 & \dots & 0 & b_n & a_n \end{pmatrix}$$

$$(\omega - H) = \begin{pmatrix} \omega - a_0 & -b_1 & 0 & \dots & 0 \\ -b_1 & \omega - a_1 & -b_2 & 0 & \vdots \\ 0 & -b_2 & \omega - a_2 & \ddots & 0 \\ \vdots & 0 & \ddots & \ddots & -b_n \\ 0 & \dots & 0 & -b_n & \omega - a_n \end{pmatrix}$$

$$(\omega - H) = \begin{pmatrix} \omega - a_0 & -b_1 & 0 & \cdots & 0 \\ -b_1 & \omega - a_1 & -b_2 & 0 & \vdots \\ 0 & -b_2 & \omega - a_2 & \ddots & 0 \\ \vdots & 0 & \ddots & \ddots & -b_n \\ 0 & \cdots & 0 & -b_n & \omega - a_n \end{pmatrix}$$

$$(\omega - H)^{-1} = \frac{1}{\omega - a_0 + \frac{b_1^2}{\omega - a_1 + \frac{b_2^2}{\omega - a_2 + \cdots}}}$$

Back to the calculation of spectra:

Recall: $(\omega - \mathcal{L}) |x, y\rangle = |\mathbf{0}, v\rangle$

Therefore:

$$\tilde{A}(\omega) = 2 \langle \mathbf{a}, \mathbf{0} | (\omega - \mathcal{L})^{-1} | \mathbf{0}, v \rangle$$

Use a recursion to represent \mathcal{L} as a tridiagonal matrix:

$$\mathcal{L} = \begin{pmatrix} a_1 & b_1 & 0 & & & \\ c_1 & a_2 & b_2 & & & \\ 0 & c_2 & a_3 & b_3 & & \\ & & \ddots & \ddots & \ddots & b_{N-1} \\ & & & & c_{N-1} & a_N \end{pmatrix}$$

And the response can be written as a
continued fraction!

$$\begin{aligned}\tilde{A}(\omega) &= 2 \langle \mathbf{a}, \mathbf{0} | (\omega - \mathcal{L})^{-1} | \mathbf{0}, \mathbf{v} \rangle \\ &= \frac{1}{\omega - a_1 + b_2 \frac{1}{\omega - a_2 + \dots} c_2}\end{aligned}$$
