Conclusion &
Outlook

1. Adding noise to classically stochastic hydrodynamics in 2D is a rich problem, which includes **Turbulence**
2. What kind of symmetries can we expect in this low-dimensional non-equilibrium problem?
3. A picture emerges from numerical simulations which points to CFT-type conformal invariance.

Outlook

- Bernard, Boffetta, Celani, Falkovich (Nature Physics (2006) 2, 124128), Showed that zero vorticity isolines conform with $c = 0$ Percolation hulls.

- Polyakov had earlier suggested a connection to CFT (with another regime in mind):
Try to match solutions of $\langle \vec{v}(x_1) \vec{v}(x_2) \dots \vec{v}(x_n) \rangle$ with CFT correlators

Strategy

1. Look at the quantum problem instead
2. Search for hidden symmetries of quantum hydrodynamics.
3. Compare to classical stochastic.

Conclusion &
Outlook

- We shall make use of Stochastic quantization (SQ) in phase space:

$$\frac{dp}{d\tau} = \imath \dot{q} - \frac{\delta H}{\delta p} + d\xi_p, \quad \frac{dq}{d\tau} = -\imath \dot{p} - \frac{\delta H}{\delta q} + d\xi_q,$$

- Take $\tau \rightarrow \infty$, whereupon $\frac{dp}{d\tau} \stackrel{d}{=} \frac{dq}{d\tau} \stackrel{d}{=} 0$
- Classically, take $\frac{d}{d\tau} \rightarrow 0$, $t \rightarrow \imath t$:

$$0 = \dot{q} - \frac{\delta H}{\delta p} + d\xi_p, \quad 0 = -\dot{p} - \frac{\delta H}{\delta q} + d\xi_q,$$

- The relation is formal.

Calogero Phase space liquid

Calogero-Sutherland Model

The Calogero-Sutherland model is an N-particle system on a line with inverse square law interactions:

$$H = \sum_i (p_i^2 + x_i^2) + \sum_{i \neq j} \frac{\theta(\theta - \hbar)}{(x_i - x_j)^2}$$

-H Reductions
-Stochastic Q of H
Reduction

-Gauge Choice
-Hydrodynamics
-Vortex Dynamics

Integrable Structure

Conclusion &
Outlook

The interaction can be thought of as a purely phase volume effect. Indeed, the dynamics are equivalent to the motion of the eigenvalues of X :

$$\dot{X} = P, \quad \dot{P} = -X$$

$$[X, P] = 2i\theta [\mathbb{1} - (N + 1)|N\rangle\langle N|]$$

The system is symmetric under $X \rightarrow U^\dagger X U$,
 $P \rightarrow U^\dagger P U$ with $U^\dagger = U^{-1}$, and $U|N\rangle = e^{i\phi}|N\rangle$.

Integrable Structure

Conclusion &
Outlook

X and P are coordinates in phase space. Since they are Matrices, we consider their Wigner transform, and the Wigner distribution

$$\hat{X} = \sum_{i,j} X_{i,j} |i\rangle \langle j|, \quad \langle x|i\rangle = H_i(x) e^{-\frac{x^2}{\theta}}$$

$$X(x, p) = \int \langle x - y/2 | \hat{X} | x + y/2 \rangle e^{i \frac{yp}{\theta}}$$

Phase Space Picture of Calogero

Susskind gave the following picture:

$$\rho(X, P) = \frac{\mathbb{1}_N(x, p)}{\{X, P\}} = \frac{\mathbb{1}_N(x, p)}{\mathcal{WT}([X, P])} = f(x, p)$$

The density is a time independent function of Lagrangian coordinates, i.e. **incompressibility**.

The ground state is given by:

$$\hat{X} = \hat{x} \cos(t) + \hat{p} \sin(t), \quad \hat{P} = \hat{p} \cos(t) - \hat{x} \sin(t)$$

where:

$$\hat{x} + i\hat{p} = \sum_{i=0}^N \sqrt{i} |i-1\rangle \langle i| = \mathbb{1}_{N \times N} a \mathbb{1}_{N \times N}$$

Conclusion &
Outlook

We want to quantize

$$\dot{\hat{Z}} = \imath \hat{Z} + \imath [\lambda, \hat{Z}]$$

where $\hat{Z} = \hat{X} + \imath \hat{P}$. With constraint:

$$[\hat{Z}, \hat{Z}^\dagger] = 2\theta (1 - (N + 1)|N\rangle\langle N|)$$

And a gauge choice determining λ

This is a **Hamiltonian Reduction**.

Conserved
Quantities

Conclusion &
Outlook

Quantize (Parisi) by introducing **Auxiliary time**, τ :

$$\begin{aligned}\frac{d\hat{Z}}{d\tau} &= -\frac{dS}{d\hat{Z}} + d\hat{\Xi} \\ &= \dot{\hat{Z}} - \imath \hat{Z} + d\hat{\Xi}\end{aligned}$$

(Ohba) Introduce Lagrange multipliers, $\hat{\nu}$ associated with the constraint, $\hat{\phi}$, and Lagrange multiplier, $\hat{\lambda}$, associated with the gauge condition, $\hat{\chi}$.

$$\frac{d\hat{Z}}{d\tau} = -\frac{dS}{d\hat{Z}} + \hat{\lambda} \frac{d\hat{\phi}}{d\hat{Z}^\dagger} + \hat{\nu} \frac{d\hat{\chi}}{d\hat{Z}^\dagger} + d\hat{\Xi} \quad (1)$$

Gauge Choice

Motivation:
Classical Stochastic
Hydrodynamics

Calogero Phase
space liquid

Stochastic
Quantization in
Hydrodynamic
(Coulomb) Gauge

Integrable Structure

-Mode Expansion

Conserved
Quantities

Conclusion &
Outlook

1. The usual gauge choice is to let \hat{X} be diagonal, $[\hat{x}, \hat{X}] = 0$.

Where \hat{x}, \hat{p} are ground state matrices.

2. This choice leads to Calogero,
$$H = \sum_i (p_i^2 + x_i^2) + \sum_{i \neq j} \frac{\theta(\theta - \hbar)}{(x_i - x_j)^2},$$
 as a Hamiltonian reduction .

3. This anisotropic choice is inconvenient. Choose instead the **Coulomb gauge**:

$$[\hat{x}, \hat{X}] + [\hat{p}, \hat{P}] = 0$$

Hydrodynamics in Coulomb gauge

Motivation:
Classical Stochastic
Hydrodynamics

Calogero Phase
space liquid

Stochastic
Quantization in
Hydrodynamic
(Coulomb) Gauge

Integrable Structure

-Mode Expansion
Conserved
Quantities

Conclusion &
Outlook

1. The equations are:
$$\frac{dZ}{d\tau} = \dot{Z} - iZ + i[\lambda, Z] + [a, \nu] + d\Xi$$
2. Considering small perturbations:
$$\hat{Z} = \hat{a}_N + V(\hat{a}_N^\dagger) + \dots$$
3. The equation of motion turns out to be:
$$\dot{V} = iV + d\xi + \dots$$
4. In vector form, $V \rightarrow \delta \vec{R}$ and
$$\vec{v} = \hat{z} \times \delta \vec{R}, \quad \delta \rho = \vec{\nabla} \cdot \delta \vec{R}, \quad \vec{\nabla} \times \delta \vec{R} = 0,$$

which leads to

$$\omega = \frac{\theta}{m} \delta \rho, \quad \vec{\nabla} \cdot \vec{v} = 0,$$

which is equivalent to hydrodynamics.

Vortex Dynamics

Motivation:
Classical Stochastic
Hydrodynamics

Calogero Phase
space liquid

Stochastic
Quantization in
Hydrodynamic
(Coulomb) Gauge

Integrable Structure

-Mode Expansion
Conserved
Quantities

Conclusion &
Outlook

1. Taking curl of Euler $\dot{v} + v \cdot \nabla v + \nabla P = 0$:

$$\dot{\omega} + v \cdot \nabla \omega = 0, \quad \dot{\rho} + v \cdot \nabla \rho = 0,$$

leads to a solution $\delta \rho \propto \omega$.

2. In our case it is only true integrated over any region whose boundary has small deformation:

$$\delta N_D = \int_D \rho(\vec{r}) d^2 \vec{r} = \frac{m}{\theta} \oint_{\partial D} \vec{v} \cdot d\vec{r} = \frac{m}{\theta} \Gamma_D.$$

3. In particular quantized vortices -

$$n_D = \frac{m}{\hbar} \Gamma_D = \frac{\hbar}{\theta} \delta N_D$$

Outlook

-Conclusion
-Outlook

1. An infinite number of conserved quantities exist and can be written through the mode expansion:

$$V = \sum_n \alpha_n a^{\dagger n},$$

where $Z = a + V + \dots$

2. The expressions are complicated, but one may expand in $\frac{\hbar}{L}$. Assuming vortices one obtains $V \sim \frac{\hbar}{L}$. One obtains a set of conserved quantities whose leading orders commute.

-Conclusion
-Outlook

$$1. \quad H_1 = \sum_n \alpha_n^\dagger \alpha_n + \dots$$

$$2. \quad H_2 = \sum \sqrt{\theta} \left(\alpha_n^\dagger \alpha_m^\dagger \alpha_{n+m} + hc \right) + (\theta - \hbar) n \alpha_n^\dagger \alpha_n + \dots$$

3. The simultaneous diagonalization of H_1 and H_2 is a problem already solved in collective field theory of Calogero and is related to Jack polynomials, CFT with $c = 1 - 12 \left(\frac{\sqrt{\theta}}{\sqrt{\hbar}} - \frac{\sqrt{\hbar}}{\sqrt{\theta}} \right)^2$
